Education in a Multilingual Society

J Cummins, University of Toronto, Toronto, Canada

Introduction

Societal multilingualism can be conceptualized in relation to two broad dimensions:

- The proportion of citizens who are fluent in two or more languages
- The degree to which languages other than the dominant language are used for purposes of social interaction within the society.

Thus, the degree to which any society is multilingual varies in relation to how many of its citizens are fluent in multiple languages and use these languages for a variety of functions in a range of social contexts. By implication, few societies can be characterized as completely monolingual in the sense that virtually every society includes individuals who use their multiple language abilities in a variety of social contexts. There is no simple cut-off point above which a society can be characterized as 'multilingual' and below which it is 'monolingual'; rather, societal multilingualism represents a continuum that is, in principle, quantifiable according to the variables outlined above.

In an era of globalization with unprecedented human mobility and social exchange, processes of language learning (and language loss) are apparent in societies around the world. Government policies attempt to influence these processes by supporting the teaching of certain languages in schools and, in some cases, by actively discouraging the maintenance of other languages, usually the languages of subordinated groups within the society (Skutnabb-Kangas, 2000).

The complexity of global multilingualism, and the challenges of language planning, can be appreciated in relation to the fact that that there are an estimated 5000 languages spoken in the world's 200 or so sovereign states and about two-thirds of all children in the world grow up in a bilingual or multilingual environment (Crystal, 1997). To illustrate, approximately half of the school populations in the Canadian cities of Toronto and Vancouver come from non-English-speaking home backgrounds. Similar linguistic diversity as a result of immigration and population mobility characterize many cities in Europe, the United States, and Australia. Other countries around the world have always been highly multilingual since their inception as nation states (e.g., India, Singapore, South Africa, Switzerland, etc.).

In the following sections, categorizations of educational provision in multilingual societies are outlined, and some of the major sociopolitical and psychoeducational issues that characterize this provision are discussed.

Categorizing Education in Multilingual Societies

The most obvious initial categorization of education in multilingual societies is whether instruction is conducted through one language exclusively or through two or more languages. Although bilingual and trilingual programs have been increasing throughout the world, partly as a result of many positive evaluations of these programs (see below), the bulk of educational provision in multilingual societies is monolingual in nature. The relative merits of monolingual versus bilingual programs will be considered in relation to the research evidence after reviewing the many complex manifestations of bilingual and multilingual education.

A variety of typologies have been proposed for categorizing multilingual education. Perhaps the best

Introduction

Societal multilingualism can be conceptualized in relation to two broad dimensions:

- The proportion of citizens who are fluent in two or more languages
- The degree to which languages other than the dominant language are used for purposes of social interaction within the society.

Thus, the degree to which any society is multilingual varies in relation to how many of its citizens are fluent in multiple languages and use these languages for a variety of functions in a range of social contexts. By implication, few societies can be characterized as completely monolingual in the sense that virtually every society includes individuals who use their multiple language abilities in a variety of social contexts. There is no simple cut-off point above which a society can be characterized as 'multilingual' and below which it is 'monolingual'; rather, societal multilingualism represents a continuum that is, in principle, quantifiable according to the variables outlined above.

In an era of globalization with unprecedented human mobility and social exchange, processes of language learning (and language loss) are apparent in societies around the world. Government policies attempt to influence these processes by supporting the teaching of certain languages in schools and, in some cases, by actively discouraging the maintenance of other languages, usually the languages of subordinated groups within the society (Skutnabb-Kangas, 2000).

The complexity of global multilingualism, and the challenges of language planning, can be appreciated in relation to the fact that that there are an estimated 5000 languages spoken in the world's 200 or so sovereign states and about two-thirds of all children in the world grow up in a bilingual or multilingual environment (Crystal, 1997). To illustrate, approximately half of the school populations in the Canadian cities of Toronto and Vancouver come from non-English-speaking home backgrounds. Similar linguistic diversity as a result of immigration and population mobility characterize many cities in Europe, the United States, and Australia. Other countries around the world have always been highly multilingual since their inception as nation states (e.g., India, Singapore, South Africa, Switzerland, etc.).

In the following sections, categorizations of educational provision in multilingual societies are outlined, and some of the major sociopolitical and psychoeducational issues that characterize this provision are discussed.

Categorizing Education in Multilingual Societies

The most obvious initial categorization of education in multilingual societies is whether instruction is conducted through one language exclusively or through two or more languages. Although bilingual and trilingual programs have been increasing throughout the world, partly as a result of many positive evaluations of these programs (see below), the bulk of educational provision in multilingual societies is monolingual in nature. The relative merits of monolingual versus bilingual programs will be considered in relation to the research evidence after reviewing the many complex manifestations of bilingual and multilingual education.

A variety of typologies have been proposed for categorizing multilingual education. Perhaps the best

known of these is Mackey's (1970) typology that distinguishes 90 different potential varieties depending on the intersection of home language(s), curricular organization of languages, and language(s) of the community and country, as well as the regional and international status of the various languages.

A less complex categorization was proposed by Cummins and Corson (1997). They distinguished five broad types based on the sociolinguistic characteristics of the languages used in the program and the population groups the program is intended to serve. Four of these program types are intended primarily for minority or subordinated group students while the fifth is intended for majority or dominant group students. These categories are not rigid, and some programs can be located in more than one category as a result of the fact that the same program serves several different groups of students.

Type I programs involve the use of indigenous languages as media of instruction and are aimed primarily at helping students of indigenous heritage acquire or consolidate their knowledge of the language. Examples include Quecha/Spanish bilingual programs in South America (Hornberger, 1988), Maori bilingual and immersion programs in New Zealand (Bishop and Glynn, 1999) and the a variety of Native language bilingual programs in the United States (McCarty, 1997). The indigenous group has usually been conquered or colonized at some time in the past, and the bilingual programs are typically aimed at revitalization of languages whose survival is threatened.

Type II bilingual programs involve the use of a national language together with a higher status or more dominant language. The national languages involved in these programs typically have long-term status in the society and often some degree of official recognition. The primary target group of Type II programs are speakers of the national language, and the program goals typically include the development of bilingual and biliteracy skills among students and reinforcement of the status of the language in the society. Examples include programs that use various African languages together with English in several African countries (e.g., Nigeria and South Africa), Gaelic in Ireland and Scotland, Welsh in Wales, Basque and Catalan in Spain, and French outside of Quebec in Canada (Baker and Prys Jones, 1997).

Type III programs involve immigrant languages that are the languages of relatively recent immigrants to a host country. Many of the bilingual programs in countries such as the United States, The Netherlands, Australia, and Sweden fall into this category. Most of these are transitional programs designed to facilitate students' overall academic progress. In some situations, Type II and Type III programs merge into one another, as in the case of some Spanish-English bilingual programs in the United States that may serve both long-term Spanish-speaking groups as well as more recent immigrant groups.

Type IV programs use manual sign languages to serve children who are deaf or hard-of-hearing. Bilingual/bicultural programs for deaf children are a relatively recent phenomenon. Scandinavian countries pioneered bilingual/bicultural programs for deaf students (Mahshie, 1995) and North American programs involving American Sign Language (ASL) followed in the early 1990s (Gibson *et al.*, 1997).

Type V programs may involve either a national language or a language of wider communication and are intended for dominant or majority group students. The primary goal is to develop bilingual and biliteracy skills among these students. Examples of Type V programs include French immersion programs in Canada (Swain, 1997) and dual language programs in the United States (Thomas and Collier, 2002). Dual language programs in the United States also fall into the categories of Type II or Type III since they serve both linguistic minority students and English L1 students with the goal of promoting bilingualism and biliteracy for both groups. The European Schools model that involves instruction in up to four languages at various points in the students' school career also qualifies as Type V (Beardsmore, 1993). Many Type II programs involving instruction through a national language can also be classified as Type V because they serve students whose L1 is the majority or dominant language as well as native speakers of the national language.

Debates and Research on Bilingual Programs

Various rationales are typically offered for implementing monolingual education in multilingual contexts. These include justifications related to educational effectiveness, ideological imperatives, and administrative/financial expediency. For example, in Western countries with significant immigrant and/or minority populations (e.g., the United States) intense debates have raged with respect to the educational effectiveness of bilingual education. Those who champion monolingual education in the dominant language argue that maximum instructional exposure to that language will result in better overall school achievement. This argument is frequently paired with the ideological justification that education should actively promote the assimilation of minority students rather than encourage them to maintain their L1 and allegiance to their home cultures. Bilingual education

in these contexts is also frequently characterized as costly and administratively cumbersome.

Debates in post-colonial contexts have covered similar ground, albeit with some differences. The educational effectiveness argument for monolingual education in the higher status language of wider communication is frequently fueled by parents' perception that this is the language of power and upward mobility. Ideological considerations that lead some governments to support monolingual education include the fact that in highly multilingual countries the former colonial language is viewed as 'neutral' and thus no favoritism is shown to competing national languages. Finally, the cost and administrative burden of developing curricula and educating teachers to teach in multiple languages are frequently viewed as prohibitive for recently independent and often impoverished nations. As a consequence, it is often seen as more administratively feasible to teach through the colonial language than to explore multilingual instructional options.

Although the arguments for monolingual education have been persuasive to many policy-makers and parents in both developed and developing countries, accumulating research evidence paints a very different picture. Evaluations in many countries have demonstrated that well-implemented bilingual and trilingual programs succeed in developing fluency and literacy in a minority language at no cost to the development of academic skills in the majority or dominant language (Spolsky, 1986; Williams, 1996; Cenoz and Genesee, 1998; Cummins, 2000; Baker, 2001; Thomas and Collier, 2002). Furthermore, although there may be increased start-up costs involved in any new program, bilingual and trilingual programs are not intrinsically more costly to operate than monolingual programs. The fact that students in bilingual programs experience no adverse academic consequences despite less instructional time through the dominant language has been attributed to the demonstrated transfer of concepts and skills across languages (e.g., phonological awareness, concepts in content areas such as science and mathematics, reading and learning strategies, etc.) (see Baker, 2001 for a review).

In summary, considerable research supports the feasibility of bilingual and multilingual programs both from the perspective of cost and overall educational effectiveness. However, effective implementation is much more likely when the ideological conditions in the wider society are favorable. In the absence of such favorable ideological conditions, educators committed to the bilingual program must work collaboratively to create a microcosm within the school where students' bilingual and bicultural identities are affirmed (Freeman, 1998).

Educational Failure

Introduction

It is a commonplace in education that some pupils fare more poorly than others. Why should this be? Why do some children seem to be at a disadvantage from first school entry and why should they continue to achieve less than others, in some cases falling further and further behind and dropping out of school at the earliest opportunity? There is, of course, any number of reasons for individual underachievement, but group disadvantage is a different matter. Certain varieties of class, race, and ethnicity that differ from majority or mainstream society (of which the school is generally representative) seem, unfortunately, to be associated with a broad area of failure. In other words, group disadvantage seems to reside, most basically, in social difference. The important issues here relate to the nature of that difference and its ramifications, and it is no overstatement to suggest that the school, as a point of contact between groups, is an arena of the greatest social and academic importance.

While educational disadvantage should not simply be equated with material poverty, there is clearly a connection and, in some quarters, 'disadvantage' has often been a euphemism characterizing the poor. In 1970, Rainwater outlined the most important historical and contemporary perspectives on poverty, all of which continue in various guises. A moralizing view depicts the poor as strong but lacking in virtue, somehow deserving of their deprived state and requiring control. However, where the poor are seen as weak, a medical assessment may be made – what was once sin is now sickness and social remediation is at least theoretically possible. Poverty viewed as a combination of virtue and weakness forms the basis of a normalizing theory; the poor are morally similar to others, but lack the resources to cope effectively. Suggested solutions to poverty would then involve providing opportunities for self-betterment. Another perspective, reminiscent of Jean Jacques Rousseau's noble savage, holds that the poor are both strong and virtuous. In this apotheosizing picture, the poor are the basic, uncorrupted, and natural inheritors of the earth. Rainwater (1970) also supplied a different view, one which goes beyond descriptive value judgment and aims to explain poverty in objective ways: this naturalizing view stresses either some version of biological determinism or cultural differences that set the poor apart and explain their lifestyles and values. Unsurprisingly, it is within this last perspective that most social scientific attempts to come to grips with poverty and disadvantage are found.

The Nature of Group Difference

Biological determinism has historically been the most pervasive of 'scientific' accounts for group disadvantage, and the "benign totalitarianism" (to cite Rainwater again) often associated with it has had racist and eugenic aims (although it may be anachronistic simply to style Victorian scientists – Francis Galton, for example – as racist in the modern sense of the term). Strong connections were established between the widespread view that some groups were inherently less capable than others, and the intelligence-testing movement begun in the 19th century by Binet, Terman, and others. Assessment of ability in ways that are now seen as clearly ethnocentric and biased in favor of social mainstreams had unfortunate

Introduction

It is a commonplace in education that some pupils fare more poorly than others. Why should this be? Why do some children seem to be at a disadvantage from first school entry and why should they continue to achieve less than others, in some cases falling further and further behind and dropping out of school at the earliest opportunity? There is, of course, any number of reasons for individual underachievement, but group disadvantage is a different matter. Certain varieties of class, race, and ethnicity that differ from majority or mainstream society (of which the school is generally representative) seem, unfortunately, to be associated with a broad area of failure. In other words, group disadvantage seems to reside, most basically, in social difference. The important issues here relate to the nature of that difference and its ramifications, and it is no overstatement to suggest that the school, as a point of contact between groups, is an arena of the greatest social and academic importance.

While educational disadvantage should not simply be equated with material poverty, there is clearly a connection and, in some quarters, 'disadvantage' has often been a euphemism characterizing the poor. In 1970, Rainwater outlined the most important historical and contemporary perspectives on poverty, all of which continue in various guises. A moralizing view depicts the poor as strong but lacking in virtue, somehow deserving of their deprived state and requiring control. However, where the poor are seen as weak, a medical assessment may be made – what was once sin is now sickness and social remediation is at least theoretically possible. Poverty viewed as a combination of virtue and weakness forms the basis of a normalizing theory; the poor are morally similar to others, but lack the resources to cope effectively. Suggested solutions to poverty would then involve providing opportunities for self-betterment. Another perspective, reminiscent of Jean Jacques Rousseau's noble savage, holds that the poor are both strong and virtuous. In this apotheosizing picture, the poor are the basic, uncorrupted, and natural inheritors of the earth. Rainwater (1970) also supplied a different view, one which goes beyond descriptive value judgment and aims to explain poverty in objective ways: this naturalizing view stresses either some version of biological determinism or cultural differences that set the poor apart and explain their lifestyles and values. Unsurprisingly, it is within this last perspective that most social scientific attempts to come to grips with poverty and disadvantage are found.

The Nature of Group Difference

Biological determinism has historically been the most pervasive of 'scientific' accounts for group disadvantage, and the "benign totalitarianism" (to cite Rainwater again) often associated with it has had racist and eugenic aims (although it may be anachronistic simply to style Victorian scientists – Francis Galton, for example – as racist in the modern sense of the term). Strong connections were established between the widespread view that some groups were inherently less capable than others, and the intelligence-testing movement begun in the 19th century by Binet, Terman, and others. Assessment of ability in ways that are now seen as clearly ethnocentric and biased in favor of social mainstreams had unfortunate

implications in eugenic practice and theory, in the passage of sterilization laws, and in immigration control, the last two being particularly important in the United States. It surely comes as no surprise to learn that assessment procedures found mental deficiency especially prevalent among the Black population, nor that many Italian, Polish, and Jewish immigrants were classified as feeble-minded compared with their British and northern European counterparts.

The ultimate excesses of the biological view were, of course, evident during World War II. The argument for innate genetic deficiency then languished until Jensen, beginning in 1969, proposed that American Blacks were indeed below the intelligence levels of normal Whites. While there was a simple and predictable charge of racism leveled against Jensen, his articles did prompt close analysis within the scientific community. Of greatest significance was the relationship between measured IQ and intelligence. Some tests are clearly biased toward particular groups: an instrument designed to measure knowledge associated with culture A would clearly be inappropriate for culture B, where intelligent behavior might take very different forms. Nevertheless, tests have been used in this inappropriate way, with predictable results. Aware of this, Jensen restricted himself to so-called culture-fair or culture-free tests, tests supposedly tapping more general ability. However, all tests, however abstract or nonverbal their form, are devised by someone at some time to measure something. A culture-free assessment is impossible. As well, some cultures are much more test-wise than others and this factor, along with elements of the context within which a test is administered, clearly influences outcomes. There is another practical point to be made here, too. Jensen found, on average, a 10–15 IQ-point difference between Black and White samples, and psychologists and educators have been virtually unanimous in saying that this difference is insufficient to warrant altered educational provision (Jensen himself had recommended different curricula for children with 'Level I' and 'Level II' ability).

Nonetheless, intelligence testing and its presumed implications for pronouncements about group heritability have continued. The studies of identical twins, which began in the 19th century (and which are virtually all flawed), were of great interest to Jensen. The now discredited work of Burt was apparently formative, and figuring in discussions by Eysenck, Kamin and others (see Edwards, 1989). The net result is that, while inheritance is clearly a factor in human life, the heritability of intelligence has not been shown to be significant for cross-group comparison – nor can it be so shown until that utopian day when differences attributable to environment and social prejudice have diminished. However, while wishing to discredit the genetic-deficiency argument, one has to warn that it is not a dead letter, either in the popular imagination or in academic circles. A psychologist in the Jensen mold emerged in the 1980s, for instance, when Rushton claimed Blacks to be inferior to Whites who, in turn, were inferior to Orientals.

Environmental deficiency has also been seen as the cause of group disadvantage, with children's poor scholastic performance attributed to inadequate and stunting physical, social, and psychological backgrounds. The patterns of socialization found among some groups have also been implicated in substantive deficit, hindering both in-school and after-school success. Thus, low socioeconomic status, large family size, absence of books in the home, disdain for the life of the mind, and, particularly, poor communication between parents and children might all contribute to disadvantage. The products of such homes have themselves been characterized as having poor language skills, poorly developed 'conscience' and academic motivation, and inability to see intellectually beyond the here-and-now and the concrete.

There are, again, real difficulties with this position. For example, the contexts that generated these observed deficits are suspect and, in any event, the latter are usually discussed in facile and overly general ways. Not enough is known about the links between early environment and these supposedly disadvantageous characteristics, nor about those between characteristics and school success or failure. How could the environmental-deficiency argument account, for example, for those many pupils who succeed despite having supposedly bad backgrounds?

The chief difficulty with the environmental position is that it is suffused with a middle-class bias. Many of the so-called deficits, for example, associated with disadvantaged children could be seen as strengths in the light of a sensitive awareness of their social situation. A poor conscience might be a sensible adaptation to dangerous and unpredictable surroundings; similarly, an inability to postpone rewards – as demonstrated in experiments in which lower-class children were much more likely than middle-class ones to take one bag of candy now rather than accept the offer of three bags in a week's time – makes good sense if previous experience suggests that promises are not always fulfilled. No one would deny that backgrounds and lifestyles differ; what is at issue here is whether or not it makes sense to translate difference into deficit.

If the environmental-deficit argument is weak, then it follows that educational innovation based upon it is flawed. This includes many varieties of compensatory education, head-start programs and

other well-meaning interventions (including proposals to completely resocialize children whose families are deemed inadequate). However, both inside and outside education, environmental deficiency continues to be seen as a strong argument in the explanation of disadvantage. Recent studies have shown that teachers – to cite one obviously important group – are still very prone to accept it (again, see Edwards, 1989 for a comprehensive review here).

If disadvantaged groups' difficulties do not spring from innate inferiorities or intellectually stunting environments, to what can be ascribed their very real educational problems? Logic and the process of elimination lead to the position that disadvantage resides in group differences, rather than in basic cognitive deficiency. Because of social comparison, and because it is clear which groups are relatively powerful and which subordinate, differences essentially become deficits. These are real enough, but it is important to realize that they are essentially **social** deficiencies. While the problems of the disadvantaged remain, their solution can now be seen to lie in the eradication of prejudice and ill-judged assessment. In some ways, this makes disadvantage even more disabling, since history suggests that problems whose existence rests upon social norms and values are among the most intractable. Even wide-ranging social revolutions and redistributions of power are unlikely to eliminate disadvantage; in the aftermath of such movements, new players may adopt new roles and the characteristics of disadvantage may alter, but the phenomenon itself seems endemic in stratified societies. This is not to say, however, that nothing can be done.

The Language Dimension

Language has a central and obvious position in social interaction and comparison. It is to be expected that 'different' language more accurately characterizes the disadvantaged than does 'deficient' language, and examining the linguistic dimension will flesh out the preceding generalities.

Sociologists and educators who studied class dialects in the early part of the 20th century generally held that lower-class speakers were both insufficiently exact and grammatically deficient, their speech being less complex in terms, for example, of phrase and clause usage. It is necessary to point out, however, that usage levels, or performance, need not relate to underlying competence (habitual performance is, of course, of some interest in its own right).

The work of the British sociologist, Bernstein (1959, 1960, 1971–1975), was significant in the analysis and explanation of lower-class language. In the 1950s, he introduced the terms 'public' and 'formal' language: the former, emphasizing emotion rather than logic, was the lower-class variant, while the latter, rich in sentence complexity, is that of the middle class (which also, however, has access to public forms). Public language is, above all, characterized by concrete and nonsymbolic expression, in which syntactic and lexical usage is restricted. Formal language, by contrast, has great symbolic and abstract expressivity. In later writings, Bernstein (1971–1975) referred to these varieties as restricted and elaborated codes.

While some of Bernstein's statements about the codes have a decidedly deficit ring to them (e.g., "the normal linguistic environment of the working class is one of relative deprivation"; Bernstein, 1960: 276), he did also note some strengths associated with public language ("simplicity and directness of expression, emotionally virile [sic], pithy and powerful"; Bernstein, 1959: 322). In the 1970s, Bernstein attempted to distance himself from any deficit interpretation and any group comparison at the level of competence, and he specifically rejected the prevailing sentiments behind compensatory education programs for the disadvantaged. Indeed, despite some of his own rather ambiguous statements, Bernstein should probably be placed within the difference camp. This does not alter the fact, however, that, whether correctly or wrongly interpreted, his work fueled the environmental-deficit argument on the linguistic contribution to educational underachievement.

The results of Bernstein's experimental studies certainly showed differences of habitual usage between groups (e.g., groups of working-class messenger boys compared with senior public-school pupils). The question, of course, is what to make of them. Many deficit theorists have had no difficulty here. The intra-family communication work done by Bernstein and his colleagues in Britain, work that reinforced the view that public-language restrictions develop from inadequate mother-child patterns, was taken up in the United States. Lower-class interactions were said to be of an imperative-normative kind, with direct and concrete language being used to maintain parental authority and control. Communication between middle-class mothers and children, however, was considered to be of a more rational and explanatory nature, setting the stage for such useful cognitive operations as generalization, logic, and planning. Indeed, in an elegant but vacuous phrase, one American research team noted that "the meaning of deprivation [is] deprivation of meaning" (Hess and Shipman, 1968: 103). All of this work is suspect. The effects of being interviewed and providing language data generally may themselves differentiate social groups; it is difficult to generalize from such data to real home interactions;

untested assumptions are made about links between variations in maternal behavior and children's developing cognitive abilities; and so on. Also, there is again in this work a strong and essentially unexamined belief in the correctness of middle-class standards and practices.

Verbal 'deprivation' was also, unsurprisingly, a powerful element in those programs of compensation underpinned by social-deficit theory. One of the most notable here began from the assumption that the lower-class (Black) child was generally retarded. Specifically, his or her language was 'immature' and 'rudimentary,' and, because of this, language was seen as 'dispensable': thus, "language for the disadvantaged child ... is not of vital importance" (Bereiter and Engelmann, 1966: 42). On this preposterous basis the authors – who had apparently never observed children from the orally rich Black culture at play – outlined a program to compensate youngsters for things they were not lacking in the first place.

None of these debatable observations about language was made by linguists, of whom virtually all have rejected the deficit philosophy from which they emerged. Many years ago, Sapir said that, "when it comes to linguistic form, Plato walks with the Macedonian swineherd, Confucius with the head-hunting savage of Assam" (Guy, 1988: 64) and, although we might not put things quite like that today, Sapir's thesis has proved convincing. Other linguists have rejected the idea of primitive mediums; while languages are not necessarily equivalent in all forms of expression, and while some may be more useful in some contexts, such dichotomies as better or worse, superior or inferior, are not applicable. More specifically, the same can be said for dialects and other varieties within a language. All forms are adequate for the needs of speakers within their own speech communities; issues of 'correctness' need to be considered with reference to each variety's own grammar, and problems generally arise only when different varieties come into contact.

In the 1960s and 1970s, this matter was thoroughly dealt with by Labov (1973) and his associates. Their test case was Black English (BE), a very good choice, since BE had long been widely perceived as a deficient and illogical approximation to proper English. The work had four important strands.

First, it was shown that the contexts in which verbal deprivation was diagnosed were generally threatening and hence inappropriate. A small Black child questioned by a large White adult typically produced "defensive, monosyllabic behavior" (Labov, 1973: 27). By simply relaxing somewhat, the formalities associated with speech elicitation, the child's performance improved dramatically, coming more to resemble that linguistic richness reflected and valued in the Black speech community.

Second, it proved possible to demonstrate that the 'restricted' speech of the lower class might well, if linguistic prejudices could be set aside, be viewed as more forceful and direct, and less redundant and verbose, than the 'elaborated' forms of the middle class. Concrete and highly charged language usage (showing, indeed, that 'pithy' quality noted by Bernstein) contrasts favorably with a more educated verbosity, which hedges basic ideas with a welter of qualification and hesitation. Of course, it can be reasonably argued that qualification and caution have a place, particularly in contexts in which difficult or abstract issues are under discussion; consequently, this second strand may be the weakest or the least completely developed. Nonetheless, it usefully challenges the received wisdom about the inevitable appropriateness of middle-class usage.

The third point of importance touched upon the competence-performance distinction. Black children were found to repeat standard English sentences in Black form. Given that the latter is a valid and rule-governed dialect (see below), and given that these repetitions exactly captured the original meaning, Labov (1973) argued that there was no evidence here at all for any inadequacy in pronunciation, grammar, or, indeed, basic cognitive ability. Children comprehend the meaning of what they hear, then (unsurprisingly) reproduce it in the form most familiar to them. The point was further reinforced by studies showing that White children repeating sentences phrased in BE typically employed standard forms.

The final, and most important, element in the overall argument dealt with specific aspects of BE grammar. The central and necessary point to be established here was that BE forms, though different (but not vastly different, incidentally) from standard ones, were adhered to as regularly as those of other varieties. Just two examples will suffice. One of the obvious features of BE is the deletion of the copula verb (in phrases like *He goin' to the store* or *We on tape*, where standard usage would produce *He is going to the store* and *We are on tape*). The copula verb **does** appear, however, in the past tense (*I was small then*). The regularity is that, in contexts where standard English permits contraction (*He is going* can become *He's going*), BE allows deletion (notice, by the way, that there is no loss in meaning, no ambiguity, in either case). Where standard usage prohibits contraction (for example, *He's as nice as he says he is* cannot become **He's as nice as he says he's*), so BE rules ban deletion. A final point here: the copula deletion traditionally condemned as inaccurate usage does, in fact,

exist in approved form in (informal) standard English too: *That your car?*, a strolling policeman might say to an illegally parked motorist.

A second example concerns such constructions as *She be standin' around* or *He be always foolin' about*, again, typically seen by White teachers and others as incorrect. Here, the *be* indicates habitual behavior and, were it absent, the BE speaker would be referring to a present action only.

These and other demonstrations convincingly make the case that BE (and, by extension, other English dialects) is a system within which grammatical rules are obeyed, not a haphazard assortment of utterances. Indeed, given what is known of human cognitive development, the rule-governed hypothesis intrinsically makes much more sense than the haphazard one, regardless of specific empirical observation, for what group, wherever and however it lived, could maintain itself adequately with a basically flawed communication system? Even so, a deficit conception of language continues in many quarters, and popular prejudices still exist toward disadvantaged forms, which are often seen as indicators of innate or acquired intellectual handicap. More worrying is that allegiance to a deficit philosophy is still evident in some academic circles.

One line of argument in such circles is that, while interventions based upon language-deficit models have been of only limited success, the models themselves are not without value. Another related suggestion is that deficit and difference theorists have typically attended to different aspects of language, with the former being mainly concerned with semantics, the latter with grammar. In either case, the linguistically overwhelming evidence against a deficit philosophy is quite incorrectly downplayed.

In 1983, Honey succeeded in muddying the waters with a monograph in which linguistic arguments supporting a difference viewpoint were rejected. Honey disagreed with the central thesis that all varieties are valid systems, claiming that this undermines attempts to reintroduce 'standards' at school and pushes disadvantaged speakers into a 'language trap.' What these persons really need, according to Honey, is assistance with standard English, but he complained that the contemporary linguistic stance, with its respect for all varieties, undercuts this and, in some cases, encourages the school to promote nonstandard forms. Detailed review of Honey's work is impossible here (though it has been undertaken by several prominent linguists, some of whom were attacked by name in the monograph), but the main points are easily summarized. First, the author has fallen prey to a confusion between concepts and the words to describe them: thus, so-called primitive groups may lack words or terms current in more 'advanced' societies, but this tells us about their physical and psychological lifestyle, not about the validity of their language (the question of why different groups develop in different ways is, of course, an interesting one, but it need have no relationship to matters of linguistic relativity). Second, in important ways Honey has misinterpreted the sort of evidence adduced by Labov (1973), which bears upon the linguistic validity of BE. Third, there is the failure to understand that language differences become deficits through the medium of popular convention and prejudice. Finally, Honey mistakenly imagined that a school policy that tolerates and does not stigmatize the use of nonstandard varieties must necessarily lead to an active fostering of these varieties (and a concomitant de-emphasis on standard forms).

Notwithstanding linguistic and other insights into the nature of language variation, it is important to remain vigilant and not to imagine that older and less informed views will simply vanish. Social psychology has long shown that the more mental energy we invest in a particular set of perceptions, the more unwilling we are to change them – even when faced with apparently unanswerable contradictions – preferring instead to engage in various forms of denial, distortion, and self-deception.

Language Attitudes

It is important to understand the evidence supporting a difference interpretation of language variety. However, it may change little in a practical sense, since it would be naive indeed to imagine that widespread diffusion of linguistic findings (assuming that were possible) would speedily eradicate incorrect perceptions. It is therefore necessary to consider in further detail those attitudes which translate language difference into language deficiency. These, it turns out, are matters with a long history; whether it is language, dialect, or accent that is discussed, preferences and prejudices tend to come to the fore. The 16th-century poet, Carew, felt that the Italian language was "pleasant, but without sinews," French "delicate," Spanish "majestical but fulsome," and Dutch "manlike, but withal very harsh." These judgments certainly reflected broad stereotypes of the day.

Dialect attitudes are most pertinent here, of course. When social comparison and inequalities of power make one dialect standard, it does not follow that others are linguistically or cognitively **sub**standard (although, if it can maintain nonpejorative status, the term 'nonstandard' is acceptable here) – a matter of *primus inter pares*, perhaps. However, works of reference have often unfortunately reinforced a

'substandard' interpretation. The Oxford English Dictionary (OED), for instance, has referred to dialect as a 'subordinate' form arising from 'local peculiarities' – a definition implicitly held by those for whom 'dialect' means some rustic or regional variety. Similarly, on accent, the OED notes 'peculiar' alterations of pitch, 'mispronunciation,' 'misplacing of stress,' and 'misinflection.' Little wonder, then, that it is still easy to find people who claim they have neither a dialect nor an accent, or to discover others eager to shed unwanted and socially stigmatized forms.

If dialects cannot be distinguished linguistically as better or worse, could it be that some are aesthetically more pleasing than others? This has certainly been a feature of much popular prejudice and, in *The Best English*, Wyld (1934) claimed that any unbiased listener would find RP (received pronunciation) the most pleasant, the most educated, and the variety best suited for formal purposes. He touched upon the heart of the matter with the word 'unbiased' – how does one obtain such a listener? Work by Giles and his colleagues attempted to illuminate this. They began by noting two basic possibilities: either some forms **are** intrinsically more pleasing than others (the 'inherent value' hypothesis) or aesthetic judgments proceed from assessments of the social standing of the speakers. To test this, judges unfamiliar with language varieties were asked to evaluate them on aesthetic grounds. In one study, Welsh adults with no knowledge of French were unable to differentiate among European French, educated Canadian French, and working-class Canadian French on this basis (even though different levels of pleasantness were found by judges drawn from **within** the French speech community). In a second experiment, English speakers knowing no Greek were asked to rate Athenian and Cretan varieties which, in the Greek context itself, are clearly marked as being of high and low status, respectively. Again, no inherent aesthetic superiority was detected. This leaves what Giles termed an 'imposed norm' explanation, one that rests upon the power of social convention and belief. The comedic effect of having a stage duchess with Cockney speech reflects ingrained and widely shared speech-community standards. A further demonstration of the purely arbitrary nature of status judgments was provided by Trudgill (1975). In England, speakers of the high-status RP do not pronounce the postvocalic *r* (in words like *cart* and *mar*), while in New York exactly the reverse holds: the higher a speaker's social standing, the more likely he or she is to sound the *r*.

More fine-grained analysis of language attitudes followed upon the introduction of the 'matched-guise' technique by Lambert and his colleagues. Here, judges evaluate recorded speakers' personality traits after hearing them read the same passage in each of two or more guises. Any rating differences can then be ascribed to language factors, since paralinguistic variables (pitch, tone of voice, etc.) are of course constant across samples. Two points are important here: first, judges must not realize that they are rating the same person using different dialects or accents (and typically they do not); second, the reasonable assumption is made that attitudes toward speech are, in fact, attitudes toward speakers: the speech acts as a trigger for a social stereotype, from which flow specific judgments, preferences, and prejudices.

Widespread use of this method in many different contexts has revealed that dialect evaluation generally involves three personality dimensions. Some dimensions of evaluation (including traits such as intelligence and industriousness) reflect a speaker's perceived competence; some (helpfulness, trustworthiness) reflect personal integrity; and some (friendliness, sense of humor) underlie social attractiveness. While, as might be expected, high-status dialects generally evoke high ratings of speaker competence, they do **not** always elicit strong perceptions of integrity and attractiveness: on the contrary, these last two (sometimes collectively seen as representing a larger, group-solidarity, dimension) are more associated with lower-class and lower-status varieties. Experimental results are, in fact, rather more involved than this summary suggests, but a reasonably fair gloss might be that higher-status speech forms are popularly associated (by both middle-class and lower-class judges, incidentally) with speaker intelligence, ambition, and drive, while the dialects of disadvantage connote trust, liking, and a general down-to-earth quality. The findings are not, then, entirely negative for the disadvantaged population by any means, but the great importance of personal competence (or the perception of it by others) remains central in educational and other settings.

Teachers' attitudes are of particular significance here since there is no reason to assume that they will diverge greatly from those of society at large, and because their perceptions may be especially salient in the definition and maintenance of disadvantage. There is a large literature on teacher expectations and the effects they have upon pupils' self-regard and scholastic progress; specifically, it has been shown that the formation of these expectations rests upon existing knowledge (and ignorance) and early assessment of children's characteristics. A child whose speech is perceived as substandard, and whose cognitive capabilities are, in turn, questioned, will be categorized and stereotyped in specific ways. There is, of course, nothing inherently wrong or unnatural with

teachers' expectations; they proceed from a universal tendency to simplify and understand a complex world which, without classification, threatens to overwhelm. But the familiar dangers of stereotyping and prejudice involve inaccurate, irrational, or incomplete categorization, often with harmful effects. Educational misperceptions based upon incorrect language assessment may create difficulties where none need exist. There is, perhaps, a special element of tragedy here inasmuch as the disadvantaged children likely to be inadequately understood in this way are exactly those children whose lives are already burdened with more tangible and inescapable weights. Experience suggests that the phenomenon of the 'nonverbal' child (to give but one example) may often be one created by teachers insensitive to cross-cultural (or cross-subcultural) differences in the domains of competition, response to authority figures, customary reaction to threat, and so on.

It is perhaps unnecessary to state that teachers are not simply and generally being accused of malice, racism, or 'classism' (although these qualities exist among them, as in the general population). Teachers are more concerned than most with the promotion of tolerance and increased social mobility. However, once installed in the classroom, there is evidence that teachers are quickly socialized into the traditional ways of the school, and this may mean a continuation of inaccurate views of disadvantage and, therefore, of disadvantage itself. Studies in the 1980s in North America and Europe have confirmed this, and have also confirmed that contemporary teachers, more tolerant of language variation than previously, still adhere in the main to a deficit view and still consider one of their major tasks to be the elimination of 'incorrect' speech patterns and the inculcation of 'proper' ones.

For example, in a study of primary and secondary teachers in Nova Scotia, Edwards and McKinnon (1987) found that disadvantage-as-deficit maintained its appeal; while teachers stressed the importance of home-background characteristics as contributors to disadvantage, they clearly viewed some environments as substantively deficient. With specific regard to language, teachers believed that disadvantaged children were incapable of properly articulating their thoughts, and generally placed little value on receptive and expressive skills (see Bereiter and Engelmann, 1966; Hess and Shipman, 1968). Minority-group children (in this study, Black and Acadian children) were particularly singled out, with Black pupils seen to have a "slang language all their own." A European review by Hagen (1987) has indicated that some countries such as France retain a centralist view of standard language, while others (the Netherlands, for example) have more liberal legislative perspectives on dialect variation, even if not always matched by school practice. Citing Dutch and Italian work, Hagen noted that nonstandard-speaking children's favorable attitudes to their own speech often decline dramatically as they grow up.

Educational Responses to Disadvantage

Language varieties associated with relatively subordinate groups are not inherently deficient, but they do possess negative connotations because of social stratification and comparisons that lead to denigration. Thus, social differences become deficits and nonstandard speech becomes substandard. While still waiting for an end to the unfair and inaccurate language perceptions that contribute to educational disadvantage and failure, it is not unreasonable to consider what schools might be doing.

First, of course, schools and teachers must become more aware of the relevant psychological and linguistic evidence bearing upon disadvantage. The wider society is generally ignorant here, so there is a real limitation on schools. On the one hand, schools tend to reflect mainstream society more than they lead it; on the other, even were schools to become centers of linguistic enlightenment, their students would still emerge into somewhat darker settings. Given these limitations, it is still quite possible for schools and teachers to be linguistically educated; the essentials of the difference-deficit argument, for example, are not difficult to grasp and do not require lengthy exposition or sophisticated prior knowledge.

Second, given the practicalities of social life, it should be assumed that a standard-language variety will continue to be important and particularly valued, and that increased mobility will be positively affected by facility with it. The recommendations made by some linguists that schools should actively encourage (in writing, as well as in speaking) nonstandard usage may seem somewhat naive. Indeed, a common accepted standard can be a leveling device rather than an exclusionary one, and a great asset in personal and group communicative efficiency. It would be a cruel irony if a rather innocent regard for all varieties resulted in a social babel where, it may be assumed, certain groups would again end up at the bottom of the heap.

Does this not bring us back to the rejected position associated with Honey? The difference is this: while it would be inappropriate and unjust for schools to neglect the standard (and while, incidentally, this would arouse great resentment on the part of disadvantaged groups themselves), a linguistically

enlightened policy demands tolerance at school for all forms. Furthermore, the best available evidence indicates that this tolerance should accompany very clear messages that mother-tongue varieties of every kind are both valid and valuable. The aim should be language-repertoire **addition**, not **replacement**: a policy of bidialectalism. Again, the evidence suggests that this is not at all an insuperable task to require of children (consider the development and maintenance of bilingual skills in suitable settings), nor need it be solely a school-based imposition. When discussing disadvantage, groups existing in the same large society are being treated; in terms of language, this means that disadvantaged groups typically have a considerable, if somewhat passive, exposure to standard forms, forms that are clearly associated with desired social contexts and rewards. The findings concerning sentence repetition indicate this latent standard facility; other evidence supports the fact that disadvantaged children, from an early age, can comprehend standard forms and, indeed, will use them themselves if they judge this appropriate. Schools, then, should activate this knowledge and make it clear to children that a broadening of their performance skills makes sense.

This is a matter of some delicacy, however, for children are being asked to accept two social facts that could easily be seen as contradictory. On the one hand, the message is that the mother-tongue variety is perfectly adequate within the home speech community, both for communicative purposes and as a vehicle of group solidarity. On the other, the child is to be made aware that a life beyond that community may require repertoire expansion. Transmission of these two messages requires tact and sensitivity based upon adequate knowledge of children's language and culture, but it will be assisted in many cases by a desire for mobility that is (unsurprisingly) strong in most disadvantaged communities. Indeed, one might note that the low regard for education supposedly characteristic of the lower class (in the deficit perspective) is much less common than a sometimes overoptimistic hope for mobility through education.

Experience, including that derived from deficit-inspired compensatory programs, suggests that formalized and drill-like language curricula make little sense. They run the risk, above all, of instilling a replacement perspective that is both uncalled-for linguistically and potentially damaging psychologically. A more laissez-faire policy seems appropriate, in which teachers act as standard-speaking models (most teachers are, in fact standard-variety speakers, either by upbringing or through their own professional socialization), and in which children's own good sense will lead to the desired expansion. Anything more formal will be counterproductive and will, at the least, contribute to an unnecessary rift between the child's school life and his or her unselfconscious participation in the community. Moreover, it should be noted again that this apparently laissez-faire policy is not simply some default option but, rather, a reasoned and aware reflection of all the evidence and insight presented here.

Recent developments in fine-grained analysis of classroom communication hold out the hopes of refining awareness and improving practices. For example, the traditional assertions that disadvantaged children's 'restricted' usage leads to difficulties with the 'elaborated' language of school are undercut by real classroom patterns, which are very often delimited exercises in control, both particularistic and concrete. Indeed, the view of schools as middle-class institutions has itself been challenged on these grounds. (While, in fact, this challenge cannot be sustained – schools **are** middle-class in the attitudes, skills, and values stressed there – there is clearly more work to be done in ascertaining classroom dynamics.)

Ethnographic analyses of classroom language have, for some time now, paid greater attention to such factors as the psychological context in which teacher-pupil interactions occur, a context in which postural configurations, direct and indirect verbal strategies, conversational rhythms, and prosody are important. These and other aspects clarify how impoverished traditional deficit-based and disembodied speech analyses are. Also central here is the interpretation of tacit school rules based upon teachers' needs for order. There is a more subtle treatment of the classroom as a speech domain in its own right, where a whole cultural code must be mastered for success. The implication is that disadvantage may be partly understood as an incomplete grasping of this code, which combines both knowledge and its appropriate display (for a seminal article here, see Mehan, 1984).

If traditional school practices required pupil adaptation in a sink-or-swim approach, while compensatory intervention programs were heavy-handed with insensitive alterations built upon insecure foundations, new approaches founded on subtle observation may help with both the school adaptation to classroom heterogeneity and a desired repertoire expansion on the part of children. Mehan's (1984) study demonstrated that detailed assessment of language styles between teachers and disadvantaged children allowed practical advice to be given to teachers about how best to adapt. This had the effect of lessening the passivity and 'nonverbality' of the pupils and, once greater participation was established, children were gradually and subtly introduced to school styles.

To reduce educational failure associated with group disadvantage, a combination of practical innovations and the transfer of existing psychological and linguistic information is needed. Ethnographic analysis of classroom discourse promises useful insights that can quickly be turned to the benefit of the disadvantaged (and their instructors). It is equally important, however, to provide teachers and others, such as speech therapists, with a much more detailed knowledge of language variation and its ramifications. While the mechanisms of disadvantage are outside the reach of school alone, there is no reason for classroom experiences to add unnecessarily to children's problems. A failure to try to ease these burdens is, in fact, a repudiation of the essence of education in a civilized society.

A Decade On

It has to be said that issues and problems have not changed greatly since this article first appeared a decade ago; the underpinnings of educational failure, in the sense discussed here, remain. The informed, academic support for the different-but-not-deficient interpretation of scholastic and linguistic disadvantage must still contend with broader and more popular views that either perceive disadvantage as substantive deficit (in more or less direct fashion) or else effectively translate difference into deficiency (through the operation of language attitudes and stereotypes, for example). Thus, the calls made above for greater general awareness of the nature of disadvantage, and for more sensitive treatment of language at school, in particular, must unfortunately be reiterated. Controversies surrounding Ebonics – as Black English has recently been styled in some quarters – provide a good example of the continuation of those heady intertwinings of knowledge and ignorance, prejudice and innocence, which we have so often seen before.

One or two of the major players mentioned above have re-entered the fray; the general impact, however, has been more to reinforce original positions than to advance understanding. Bernstein (1997: 47) has discussed the context within which his code theory was formulated and presented, and – rather disingenuously – observed that the difference/deficit debate was "of little theoretical significance" and "obscured more than it revealed." He also offers here an analysis of Labov's 1973 paper, but pays no attention to the grammatical aspects that were characterized (above) as the most important element in the overall argument. An interesting defense of Bernstein and his work has been mounted by Robinson (1998), who correctly points out that many of the views for which Bernstein was most vilified were not, in fact, his views at all. Robinson also maintains that academic criticism of Bernstein was essentially nonconstructive, not "Popperian-based", and often personalized. However, while such criticism certainly arose in some quarters, it would be a mistake to imagine that more measured treatments were absent (see Edwards, 1989). In a book published in 1997, Honey has re-emphasized his views (initially expressed in 1983) of standard and nonstandard language, views that have attracted considerable criticism for reasons already discussed here (see above). More recently, Honey (1998) suggested that academic criticism of his thesis is marred by false argument and innuendo.

In general, then, it is fair to say that the social conditions and the social prejudices that produce and maintain the educational failure associated with group disadvantage are still very much with us. It is also fair to say that much of the discussion of the issue – within and without the academic cloister – continues to generate more heat than light.

The Emergence of Educational Linguistics

By all accounts, educational linguistics as a defined area of study began in the 1970s with the work of Bernard Spolsky, who first put forth the term in a 1972 conference paper and later produced the seminal introductory monograph on the topic in 1978. He originally envisioned educational linguistics as a sub-field of linguistics, much like educational psychology and educational sociology are subfields of their disciplines proper, that would specifically address the broad range of issues related to language and education.

He positioned his educational linguistics in relation to applied linguistics, which, he noted, encompassed a broader territory of practical language issues. Educational linguistics has, indeed, continued to develop in tandem with applied linguistics, which has come a long way since the middle of the 20th century (Markee, 1990; van Lier, 1994). There is less than total agreement as to what the relationship between the two is, however. Some scholars, for example, identify themselves as linguists who are applied linguists who are educational linguists (e.g., van Lier 1997: 95), whereas others, pointing to its unique objectives and goals, distinguish educational linguistics as a field unto its own (e.g., Christie, 1994: 97; Hornberger, 2001: 5). What is clear, however, as Hornberger (2001: 19) points out, is that educational linguistics has developed a unique niche in that its "starting point is always the practice of education and the focus is squarely on (the role of) language (in) learning and teaching." It is in filling this niche that educational linguistics has found its place in a variety of contexts around the world.

Three Schools

Internationally, educational linguistics seems to have taken shape in three major ways, or in what might be considered loosely the British, the Australian, and the American schools. Each is distinctive in a number of ways.

The British School may be the most closely coupled with general linguistics as seen in the efforts to make linguistics a foundational area of teacher training (Brumfit, 1997; Stubbs, 1986), as well as attempts to create curricula based on linguistic principles (Carter, 1990, cited in Christie, 1994: 96). At the same time, British educational linguistics cannot be said simply to be the marriage of linguistics with education. On the one hand, there has not been universal agreement as to how linguistics should relate to education, leaving much to be done on this front by both linguists and educators (Hudson, 2004). On the other hand, following the lead of an applied linguistics that synthesizes multiple disciplinary approaches, British educational linguists also draw on a wide constellation of research tools beyond those offered by linguistics alone (Brumfit, 1996; see, for example, Creese, 2003).

Australian educational linguistics stands out for its clear connection to systemic functional linguistics, in particular. Here, systemic functional linguistics, in which language is viewed as a social semiotic that is part and parcel of creating and interpreting social context, is brought together with other social sciences

The Emergence of Educational Linguistics

By all accounts, educational linguistics as a defined area of study began in the 1970s with the work of Bernard Spolsky, who first put forth the term in a 1972 conference paper and later produced the seminal introductory monograph on the topic in 1978. He originally envisioned educational linguistics as a sub-field of linguistics, much like educational psychology and educational sociology are subfields of their disciplines proper, that would specifically address the broad range of issues related to language and education.

He positioned his educational linguistics in relation to applied linguistics, which, he noted, encompassed a broader territory of practical language issues. Educational linguistics has, indeed, continued to develop in tandem with applied linguistics, which has come a long way since the middle of the 20th century (Markee, 1990; van Lier, 1994). There is less than total agreement as to what the relationship between the two is, however. Some scholars, for example, identify themselves as linguists who are applied linguists who are educational linguists (e.g., van Lier 1997: 95), whereas others, pointing to its unique objectives and goals, distinguish educational linguistics as a field unto its own (e.g., Christie, 1994: 97; Hornberger, 2001: 5). What is clear, however, as Hornberger (2001: 19) points out, is that educational linguistics has developed a unique niche in that its "starting point is always the practice of education and the focus is squarely on (the role of) language (in) learning and teaching." It is in filling this niche that educational linguistics has found its place in a variety of contexts around the world.

Three Schools

Internationally, educational linguistics seems to have taken shape in three major ways, or in what might be considered loosely the British, the Australian, and the American schools. Each is distinctive in a number of ways.

The British School may be the most closely coupled with general linguistics as seen in the efforts to make linguistics a foundational area of teacher training (Brumfit, 1997; Stubbs, 1986), as well as attempts to create curricula based on linguistic principles (Carter, 1990, cited in Christie, 1994: 96). At the same time, British educational linguistics cannot be said simply to be the marriage of linguistics with education. On the one hand, there has not been universal agreement as to how linguistics should relate to education, leaving much to be done on this front by both linguists and educators (Hudson, 2004). On the other hand, following the lead of an applied linguistics that synthesizes multiple disciplinary approaches, British educational linguists also draw on a wide constellation of research tools beyond those offered by linguistics alone (Brumfit, 1996; see, for example, Creese, 2003).

Australian educational linguistics stands out for its clear connection to systemic functional linguistics, in particular. Here, systemic functional linguistics, in which language is viewed as a social semiotic that is part and parcel of creating and interpreting social context, is brought together with other social sciences

in order to study language use in educational practice as a socially situated process (Christie, 1994; Martin, 1998). A central focus of the Australian School has been the teaching and learning of genre in literacy for professional and academic purposes (e.g., Christie and Martin, 1997). It also is worth pointing out the loose connection between the British and the Australian schools because of Halliday's influence on both the beginnings of British educational linguistics and the growth and development of educational linguistics in Australia (see Halliday *et al.*, 1964, for an early influential work; see also Hudson, 2002).

The American School is characterized by its diversity of topics and conceptual underpinnings. Aspects of general linguistics are brought together regularly with the research tools of other social sciences, most often anthropology, psychology, and sociology, to investigate the totality of issues related to language acquisition, language use, and sociolinguistic context in formal and informal education (Hornberger, 2001). In addition to Spolsky, Hymes has been an influential figure in American educational linguistics, especially in the early days, and his perspective on sociolinguistics (e.g., Hymes, 1974) has been drawn on in a great deal of research under the rubric of educational linguistics, especially in the United States.

It should be noted, of course, that the British, Australian, and U.S. contexts are not the only sites where educational linguistics has emerged. The principles of educational linguistics have been put to use in a variety of settings; for example, Pakir (1994) describes the use of educational linguistics to examine the role of multilingualism and cross-cultural communication for education in Singapore; and in Argentina, Suardiaz and Domínguez (1987) take an educational linguistics perspective in considering the role of the native language in elementary education, as both instrument and object of the educational process and as means of evaluating that process. The importance of educational linguistics for other contexts also can be seen in the establishment of training programs in various parts of the world, which will be discussed later.

Taking Stock of the Field

Despite the clearly identifiable (albeit nonexclusive) trends in what we call the three schools of educational linguistics, there is much common ground and activity. Educational linguistics is characterized by certain core features that, by and large, all approaches to educational linguistics share. In particular, we highlight the tendency toward transdisciplinarity that, although latent in Spolsky's formulation, is increasingly gaining prominence. We then pause to reflect on academic and professional developments including the establishment of degree programs and the publication of core texts.

Defining Characteristics

Fundamentally, as Hornberger (2001) shows, educational linguistics can be characterized as a field with a dynamic relationship to a range of disciplines which takes a problem-oriented approach to issues focused squarely on language in or around education, yielding analytical scope with depth on these issues. Accordingly, educational linguistics has a broad scope and a narrow focus.

The interface of linguistics with other disciplines has always been a core feature of educational linguistics. As Spolsky remarks, it "start[s] with a specific problem and then looks to linguistics and other relevant disciplines for their contribution to its solution" (1978: 2). Its scope, he continues, "is the intersection of linguistics and related language sciences with formal and informal education" (1978: 2). The potential set of problems to be examined is, of course, unquestionably vast, as are the possible combinations of research tools that could be used to investigate them. This does not mean, however, that educational linguistics is adrift in an ocean of research prospects. Rather, as a field, it is "pluri-centric, multi-method, and multi-level" (Kjolseth, 1978, in reference to Sociology of Language). That is to say, there are, as the entries in this section of the encyclopedia indicate, multiple core issues at the heart of educational linguistics, which demand different sets of research methods. Thus, a broad scope is achieved through the range of work done under the auspices of the field and depth is accomplished through intricate investigations by individuals with expertise in specific areas. Each educational linguist approaches research in different ways, some focusing on micro-level issues, some on macro-level issues, and others on the connections between them. The result is a holistic, or transdisciplinary, understanding of the interplay among individuals, language, society, and education.

From Interdisciplinary to Transdisciplinary

Educational linguistics came of age in a dynamic moment in intellectual activity, particularly in the area of language study which also saw the birth of Fishman's sociology of language (Fishman, 1968, 1972) and Hymes's ethnography of communication (Hymes, 1972; see Joseph, 2002, and Murray, 1998, for discussions on the history of [socio]linguistics). It is not surprising, then – given this climate that eschewed disciplinary boundaries in favor of the holistic study

of specific issues – that educational linguistics emerged as problem-oriented and interdisciplinary. Spolsky suggested that linguistics, although central to the study of language-related issues, must be synthesized in a complementary manner with the approaches of other disciplines in order to comprehend fully any specific problem (viz. issue or theme) related to language and education (1978: 2–3). It is here that the seeds of transdisciplinarity in educational linguistics were first planted.

Writing on the subject of applied linguistics more broadly, Halliday (2001: 176) stated:

> I say 'transdisciplinary' rather than 'inter-' or 'multidisciplinary' because the latter terms seem to me to imply that one still retains the disciplines as the locus of intellectual activity, while building bridges between them, or assembling them into a collection; whereas the real alternative is to supercede them, creating new forms of activity which are thematic rather than disciplinary in their orientation.

Halliday remarks that activities in applied linguistics "involve more than the content of any one discipline: at the very least, they involve psychology, sociology, and linguistics" (2001: 176) and he offers foreign language teaching as an example. In his call for a transdisciplinary applied linguistics, he notes that the aim should be not simply to create an amalgam of intellectual activity made up of a collection of features from a variety of disciplines but to go further and synthesize what each relevant discipline has to offer on a particular issue. By doing this, the focus becomes theme-based. A theme, he explains, "is defined not by content but by aspect, perspective or point of view" (Halliday, 2001: 176). In this way, Halliday suggests, the focus of intellectual activity would not be on building bridges across disciplinary content areas but, rather, on synthesizing specific research tools (which are often, although not always, disciplinary-based) to investigate a particular theme or issue. It is a fine distinction but an important one.

The starting point is at the core of the difference between inter-/multidisciplinarity and transdisciplinarity. In inter-/multidisciplinary inquiry, the research begins with what is knowable from the point of view of specific disciplines and how, by building bridges across them, a researcher can achieve a more vibrant picture than one would be able to view from the vantage point of a single discipline alone. In a transdisciplinary orientation, research begins with a theme – an aspect (a specific issue, concern, problem) of a specific situation – and then uses the resources at one's disposal to investigate that theme. This, to use Halliday's words, removes the locus of intellectual activity from the disciplines, thereby superseding them to place the locus of intellectual activity around the theme itself. The transdisciplinary researcher is like a painter who creates a multidimensional picture of a particular theme by using the spectrum of research tools on her or his palette.

Following Spolsky's characterization of educational linguistics as problem-oriented, it is easy to see how it is best considered transdisciplinary. Problem-oriented is similar in spirit to theme-based in Halliday's formulation of transdisciplinarity. In each case, the idea is that a researcher not simply take disciplinary knowledge and apply it to a situation. In educational linguistics, a researcher begins with a problem, issue or theme, related to language and education and then synthesizes the research tools in her/his intellectual repertoire to investigate or explore it. The work of educational linguistics, then, is carried out in and across a variety of academic departments (anthropology, area studies, education, English, foreign languages, linguistics, psychology, sociology, etc.) depending on the theme. This is, incidentally, how the pioneering anthropological linguist Edward Sapir envisioned that *all* research in linguistics should take place (Anderson, 1985: 219–221). In this way, educational linguistics follows in a tradition of linguistics broadly conceived. The Australian School has long taken this approach, characterizing educational linguistics as a transdiscipline (Martin, 1993: 141).

The theme-based nature of a transdisciplinary educational linguistics also serves to highlight another crucial element of this field – research/practice reflexivity. Research in educational linguistics is not done for the sake of knowledge alone but, rather, with the aim of addressing a particular aspect of a practical concern to formal and/or informal language education. Thus, the aim of research is to impact on practice. This is a two-way street, however. What is done in the practice of formal and/or informal education often serves as the impetus for research. In this way, themes to be investigated are not generated exclusively in the mind of a researcher but from the researcher's contact with practice. In educational linguistics research and practice feed off of as well as inform each other (Freeman, 1994; Myers, 1994; Pica, 1994).

From its beginnings, the field of educational linguistics has been concerned with the study of all the factors that influence language use as it relates to education. The objective has always been the creation of a thorough and articulated body of knowledge about these factors, and relationships among them, for the purpose of advancing educational issues ranging from language acquisition to language planning. Clearly, no single paradigm or discipline could suffice for such an endeavor and, consequently, educational

linguistics is likely to continue to evolve as a transdisciplinary field, bound not by a disciplinary base but by its single focus.

Professional Activities

Since the founding in the early 1970s of the first two doctoral programs in educational linguistics at the University of New Mexico, by Spolsky, and at the University of Pennsylvania, by Hymes and Wolfson (Hornberger 2001), a number of academic training programs specifically in educational linguistics have grown around the world. Doctoral programs with a concentration in educational linguistics have been established at Arizona State University, Stanford University, The University of Manchester, the University of Newcastle upon Tyne, and the University of Warwick. Master's level training in educational linguistics has been created at Lancaster University, Srinakharin Wirot University, and the University of Colorado, Boulder. Coursework in educational linguistics is offered at universities in Australia, Canada, New Zealand, Saudi Arabia, the United States, and probably elsewhere as well. In addition, the University of Groningen hosts the Educational Linguistics Research Group and the Monterey Institute of International Studies offers master's degrees in TESOL and TEFL through its Graduate School of Language and Educational Linguistics. Educational linguistics is clearly becoming firmly institutionalized (see Relevant websites).

Intellectual activity in educational linguistics also has been strong since the early 1970s. The first foundational book, alluded to earlier, was Spolsky's (1978) *Educational linguistics: an introduction* followed by Stubbs's (1986) *Educational linguistics*. Developments continued in the 1990s when educational linguistics was a featured topic of the Georgetown University Round Table on Languages and Linguistics (Alatis, 1994) as well as the subject of other conference presentations (e.g., Brumfit, 1996; van Lier, 1999). The *Concise encyclopedia of educational linguistics*, an impressive summary of work in the field, edited by Spolsky, was released in 1999. Most recently, Kluwer Academic Publishers inaugurated its *Educational linguistics* book series with van Lier as general editor. Although there is as yet no professional organization or peer-reviewed journal devoted to educational linguistics, the student-managed *Working Papers in Educational Linguistics* (www.wpel.net) has continuously published work since 1984. Individual educational linguists have published and presented their work in a variety of venues since the beginning and they continue to have a strong presence in linguistics and related social sciences.

Future Directions

Lamentably, as Gee reminds us, "linguistics has had much less impact on education, and teachers know much less about language and linguistics, than the current state of our knowledge about language in education, or the current dilemmas of our schools, would seem to merit" (2001: 647). After depicting how differing theories of language arising from functional and generativist linguistics, respectively, play a role in major educational debates (such as that around whole language vs. phonics instruction), Gee goes on to exemplify some of what we do know about language in education, including the role of overt focus on language in helping children acquire new forms of academic language, the need for teachers to understand the diverse linguistic and cultural resources children bring to their classrooms, and the ways in which language form and meaning are interactionally worked out in moment to moment classroom interaction. He argues, then, as other educational linguists have before him, that we need to do a better job of putting what we know in linguistics into practice in schools.

As pressure builds on the educational systems of the world to serve the needs of increasingly diverse multilingual populations and at a time when multilingualism and multiliteracy are clearly becoming socially and economically advantageous, the need to understand relationships between language and education is particularly acute. The more the complexity of the relationships between language and education is recognized, the more complex research must become, in turn. Transdisciplinary work is likely to be more important than ever before. Although educational linguistics as a field has tended in this direction since the beginning, there is much to be done to build a truly unified and coherent body of knowledge. Although all educational linguists seem to share the common goal of fostering education that is linguistically appropriate and socially responsible, there is little strategic dialogue on how to realize this goal on a grand scale. As a whole, then, educational linguistics seems to lack a clear course. If educational linguistics is to emerge as an articulated transdiscipline that encompasses all issues in language and education, it is time to seek out the connections and relationships among all the individual and societal topics that are studied at micro-, meso-, and macro-levels. Recent trends in ecological research are promising in this regard.

Although ecological approaches are not new to the social sciences, they have recently gained prominence in educational linguistics. Van Lier (1999), for example, emphasized the importance of integrated multidimensional inquiry over the decontextualized study

of discrete variables when trying to understand matters related to language and education, which are all socially situated. In this vein, an ecological approach is increasingly used in the study of all facets of educational linguistics, from individual-level language acquisition to classroom pedagogy to language policy. For instance, Leather and van Dam's (2003) *Ecology of language acquisition*, the first text released in Kluwer's *Educational linguistics* series, features a collection of articles that consider the complex contextual factors that influence language acquisition. In addition, Hornberger's (2003) *Continua of biliteracy: an ecological framework for educational policy, research, and practice in multilingual settings*, also an edited volume, highlights the value of synthesizing multiple levels of analysis in order to fathom the intricacies of constructing, implementing, and evaluating educational programs for bi-/multilingualism. Although these books reflect different perspectives on ecology, they share the understanding that the processes involved in any aspect of language and education cannot be effectively studied in isolation. It is in this sense that ecology is likely to play a central role in the future of educational linguistics.

Consistent with the early core characteristics of the field, these ecological approaches in educational linguistics are problem-oriented and interdisciplinary. At the same time, the theme-focused holism in these approaches moves the field more firmly toward transdisciplinarity, making a strength of drawing on multiple disciplines to create a holistic portrait of (the role of) language (in) teaching and learning. In all, educational linguistics, as it has done throughout its short history, is certain to remain grounded in its core principles while adapting to fit the needs of research and practice in an ever-changing multilingual world.

Efik

B Connell, York University, Toronto, ON, Canada

© 2006 Elsevier Ltd. All rights reserved.

Background

Efik is one of the better-known African languages and was at one time one of the best-described African languages. It is spoken today by perhaps 750 000 people as a first language in the southeastern corner of Nigeria, in and around the city of Calabar, its cultural center. Due to its location near the Atlantic coast, Calabar and the Efik were encountered early by European explorers, traders, and missionaries. Calabar was a major slave port during the era of the trans-Atlantic slave trade. As a result of its strategic location, Efik became the dominant language of the region, and for a considerable period was used inland along the Cross River as the local trade language. As a result of missionary activity in the mid- to late-1800s, Efik became one of the first languages of sub-Saharan Africa to be reduced to writing. A sketch grammar was published in 1857 (Goldie, 1857), followed by the first Efik-English dictionary in 1862 (Goldie, 1862). Insights from Efik data were important in the development of our current understanding of tone and its place in phonology (Ward, 1933; Welmers, 1959; Winston, 1960), leading to the notion of downstep and indirectly to the advent of autosegmental theory. In recent years Efik has been eclipsed in prestige locally, and it has given way to English and Nigerian Pidgin as lingua francas in Southeastern Nigeria. Despite its early development, only a small literature has accrued in the language; it is used to some extent on radio and television, but there is no Efik language newspaper. Goldie (1857) remains the only attempt at a grammar of the language, and except for the work of T. L. Cook (Cook, 1969, 1985, 1986, 2002), it has largely escaped the notice of contemporary linguists.

Classification

Efik is now recognized as part of Lower Cross, a subgroup of Cross River, which is in turn a branch

Efik

B Connell, York University, Toronto, ON, Canada

© 2006 Elsevier Ltd. All rights reserved.

Background

Efik is one of the better-known African languages and was at one time one of the best-described African languages. It is spoken today by perhaps 750 000 people as a first language in the southeastern corner of Nigeria, in and around the city of Calabar, its cultural center. Due to its location near the Atlantic coast, Calabar and the Efik were encountered early by European explorers, traders, and missionaries. Calabar was a major slave port during the era of the trans-Atlantic slave trade. As a result of its strategic location, Efik became the dominant language of the region, and for a considerable period was used inland along the Cross River as the local trade language. As a result of missionary activity in the mid- to late-1800s, Efik became one of the first languages of sub-Saharan Africa to be reduced to writing. A sketch grammar was published in 1857 (Goldie, 1857), followed by the first Efik-English dictionary in 1862 (Goldie, 1862). Insights from Efik data were important in the development of our current understanding of tone and its place in phonology (Ward, 1933; Welmers, 1959; Winston, 1960), leading to the notion of downstep and indirectly to the advent of autosegmental theory. In recent years Efik has been eclipsed in prestige locally, and it has given way to English and Nigerian Pidgin as lingua francas in Southeastern Nigeria. Despite its early development, only a small literature has accrued in the language; it is used to some extent on radio and television, but there is no Efik language newspaper. Goldie (1857) remains the only attempt at a grammar of the language, and except for the work of T. L. Cook (Cook, 1969, 1985, 1986, 2002), it has largely escaped the notice of contemporary linguists.

Classification

Efik is now recognized as part of Lower Cross, a subgroup of Cross River, which is in turn a branch

of Benue-Congo and part of the Niger-Congo phylum (Connell, 1994). Linguists working on the classification of African languages have frequently noted similarities between Efik and Bantu, (e.g., Guthrie, 1967–1971; Greenberg, 1963; see also Winston, 1970), though without advancing the claim that Efik or its sister Lower Cross languages are themselves Bantu or Bantoid. Other members of the Lower Cross grouping include Ibibio and Anaang, which, despite interesting structural differences among the three, exhibit a fair degree of mutual intelligibility, Ekit, Oro, Obolo, Usaghade, and a number of other smaller languages. The variety of Efik spoken at Calabar is considered the standard form of the language; there are minor dialect variations, spoken at neighboring Creek Town and to the northwest of Calabar in the Odukpani area. The brief descriptive notes that follow are confined to remarks on certain interesting aspects of the Efik tone system.

Efik Tone

Efik is a classic example of a two-tone (high, low) terrace-level register tone language exhibiting both 'automatic' and 'nonautomatic' downstep. Thus, after H there exist only three possibilities: H, L or downstepped H ($^{\downarrow}$H), and after L only H is possible. H after L and $^{\downarrow}$H are both lowered relative to a preceding H (i.e. 'automatic' and 'nonautomatic' downstep, respectively) and no subsequent H within the same phonological phrase can rise above this new level, hence the terracing effect. H and L can combine within the same syllable to give surface contours, both rising (LH) and falling (HL). Lexical roots in Efik fall into one of three tone classes, those bearing H, L, or LH tone patterns.

Tone functions both lexically and grammatically in Efik. At the lexical level, there is an abundance of minimal pairs that establish this function. Grammatically, tone is used to mark a wide range of functions. In the noun phrase, associative and genitive constructions, whether adjective + noun or noun + noun, are indicated by means of a modification of the tone of the second element of the construction. In the verb phrase the positive imperative form of the verb is considered to bear the inherent tone; certain tenses, aspects, and moods, and focus and negation are indicated through tone modifications. Person (2SG vs. 3SG, 2PL vs. 3PL) is marked through a modification of the tone of a prefix. Together with tense and aspect, focus in Efik may be considered a basic category of the verb system. A very brief and partial sketch only of its operation is possible here; the interested reader is referred to Cook (1985, 2002) for further details.

Focus is marked by means of an inflectional affix, normally consisting of one or more tones, attached to the verb stem. On positive verbs, a three-way distinction is made, where focus is on the verb itself (verb phrase focus, VPF), on a word or words preceding the verb (PrVF), or on a word or words following the verb (PoVF). Thus, a verb with the same time and aspect reference will vary in its tone according to its focus condition. Verbs bearing inherent H become in the past, for 1SG, $^{\downarrow}$H (VPF), H (PrVF), and L (PoVF); verbs with inherent L remain L under these conditions. For negative verbs only a two-way distinction is realized, between PrVF on one hand and VPF and PoVF on the other.

This article has given only a brief insight into the complexity of one aspect of Efik, its tone system. Other aspects of Efik structure, both in the realm of phonology and in syntax, as well as elsewhere, are equally interesting. Renewed focus on this language would well repay linguists for their efforts.

Egypt: Language Situation

J Battenburg, California Polytechnic State University, San Luis Obispo, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Arabic in Egypt is the dominant language, and as in other Arab countries, diglossia is found in which 'higher' varieties such as Classical Arabic and Modern Standard Arabic exist alongside 'lower' colloquial varieties, which themselves are represented by local dialects. Other languages represented in Egypt, however, include Nubian, Kenuzi-Dongola, Domari, Berber, and Coptic. With a rapidly growing population of 76 million and a literacy rate of approximately 57%, Egypt continues to grapple with challenges concerning language preference and use.

Classical Arabic, the language of the Islamic tradition, is of course used in reciting the Koran, while Modern Standard Arabic is employed in religious sermons, contemporary literature, newspapers, news broadcasts, and academic writing. Modern Standard Arabic is learned at school and colloquial varieties are acquired at home. Although most educated Egyptians are able to comprehend Modern Standard Arabic in listening and reading, considerable variation exists in their ability to produce this form in speaking and writing.

Spoken Egyptian Arabic (Arabic, Egyptian Spoken), sharing features with Eastern Arabic spoken in the Levant and the Gulf is commonly used in everyday oral communication and is also the language of much film and television beamed throughout the Arab world. Varieties of Egyptian Arabic include the more prestigious urban dialect of Cairo, the dialect of Alexandria as well as rural dialects including Arabic spoken in the Delta, in the Oases and Sinai by Bedouins (known as Arabic, Eastern Egyptian Bedawi Spoken), and in Middle and Upper Egypt (known as Saidi Arabic).

Domari speakers represent the largest language minority group in Egypt, with over one million members. The Domari, referred to as Muslim Gypsies, trace their origins to India in the 18th century and are spread out in communities in North Africa and the Middle East. Both Nubian and Kenuzi-Dongola are spoken in Egypt as well as in Sudan and share lexical similarities. The Nubian language is spoken by approximately 200 000. With the construction of dams along the Nile, Nubians have either relocated to new villages or moved to larger cities. Kenuzi-Dongola speakers, many who also live in the Upper Nile Valley, are estimated to number approximately 100 000. Only about 5000 Berber speakers are found in the western desert of Egypt. Finally, Coptic, the original language of Egypt, is only used today in liturgies of the Coptic Christian Church. Although used almost exclusively for religious practices, a handful of Coptics have been involved in an attempt to revive the Coptic language.

Foreign languages commonly spoken in Egypt include English, French, and German. English, of course, is required in the curriculum from grade seven on through secondary school, and many private schools use English and to a lesser extent other modern European languages as one of the main languages of instruction.

As elsewhere in the Arab world, Egyptians continue to view mastery of Modern Standard Arabic as well as of English and other modern European languages as a means for socioeconomic mobility as well as a tool for modernization and privatization.

Egypt: Scripts, Ancient

L Depuydt, Brown University, Providence, RI, USA

© 2006 Elsevier Ltd. All rights reserved.

Setting

Rising from obscure beginnings around 3000 B.C.E., ancient Egyptian civilization flourished in the Nile Valley for more than three millennia. In 332 B.C.E., Alexander the Great conquered Egypt. Greek writing, language, and culture became dominant among the upper classes concentrated in the cities. In 30 B.C.E., Rome annexed Egypt. The land lost its independence until modern times. The Pharaonic state ceased to exist. However, its distinctive culture endured for several hundred more years. It was the irrepressible expansion of Christianity, especially from the 4th century C.E. onward, that finally extinguished both Egyptian religion and hieroglyphic writing, which had become exclusively religious in purport, probably in the 6th or 7th century C.E. Pharaonic culture had by then retreated to remote holdouts in the deep south near Assuan. The advent of Islamic religion and Arabic language in the 7th century C.E. led to the extinction of the last stage of the Egyptian language, Coptic, some time between 1000 and 1500 C.E. Since the 3rd or 4th century C.E., literate Christians had begun writing the Coptic language with the Coptic script, which is the Greek alphabet supplemented by a few characters derived from hieroglyphic writing for sounds not expressed in Greek. Coptic survives to this day in the liturgy of the Christian–Egyptian, or Coptic, church. However, the language was hardly understood by many at the beginning of the modern age.

Ancient Egyptians used the hieroglyphic script to write their language. The script is pictorial. The unit is the hieroglyph. Hieroglyphs are stylized but fairly realistic pictures of divine and human beings and all sorts of objects. Earliest hieroglyphic writing, from approximately 3000 B.C.E., possibly earlier, consists of imperfect attempts that are often difficult to decipher. Full-fledged hieroglyphic writing emerges around 2500 B.C.E. In the 2nd century C.E., the hieroglyphic writing tradition began a steep decline, yielding to the Greek and Coptic scripts. The latest explicitly dated hieroglyphic texts belong to the 4th and 5th centuries C.E. The last scribes who could write hieroglyphs to any degree presumably died in the 6th or 7th century C.E., did we but know their names. The script therefore needed to be recovered from total oblivion. Jean François Champollion deciphered hieroglyphic writing in 1822. A key insight came to him on September 14, 1822. That day is widely regarded as the date of birth of Egyptology.

'Hieroglyphic' is a Greek term used by Clement of Alexandria (ca. 150–215 C.E.). It means 'pertaining to (*ic*) holy (*hiero*) carving (*glyph*).' Strictly speaking, the term denotes only the most conspicuous use of hieroglyphs, found in monumental texts incised on temple and tomb walls. Broadly speaking, hieroglyphic refers to all types of hieroglyphic writing, including some so cursivized that most signs are no longer recognizable as pictures.

Structure

Language and Writing: The Sign

Writing represents language. Describing a writing system therefore begins with the structure of language. Language consists entirely of signs – de Saussure's *signes linguistiques*. Signs have two sides, a signified and a signifier. An example of a signified is the image one has of a dog. An example of a signifier is the sound pattern consisting of the three sounds $d + o + g$ or, better, the code in the brain that can induce the speech organs to produce these sounds. The independent existence of signified and signifier is self-evident from comparing languages. Speakers of French possess the same signified. However, a different sound pattern serves as signifier, *chien*. The fact that in shifting from English to French, the image of a dog stays more or less the same whereas the sound pattern changes proves the distinction between signified and signifier. However, language is neither signifieds nor signifiers. It is the links between the two. Speakers consent, as it were, to link the image of a certain animal always to the same sound pattern, *dog*. Native speakers do so in childhood, and others do so when learning English as a second language. The electrochemical configurations in the brain of signifiers, signifieds, and links between them remain unknown. However, their existence seems certain by inference.

Hieroglyphs are pictures of people and things. How do pictures come to represent the language? Languages are made up of signs. Signs are two-sided. Symbols therefore represent signs in two ways. They refer either to signifieds or to signifiers. Hieroglyphic writing is one of a handful of scripts that exhibit both ways.

The Ideogram

A hieroglyph denoting a signified (i.e., the image one has of something) is an ideogram – that is, an 'idea' (*ideo*) 'character' (*gram*). Examples are the hieroglyph 𓁹 depicting a head in the word 𓁹𓏏 *tp* 'head,' 𓃭 depicting a lion in 𓃭𓅱 *rw* 'lion,' and 𓂋 depicting

a house in 𓉐 *pr* 'house'; the 'ideographic' stroke in these words marks hieroglyphs simultaneously as an ideogram and as sole symbol denoting a word. The relation between picture and person or object depicted differs from ideogram to ideogram.

The Phonogram

A hieroglyph denoting a signifier (i.e., one or more sounds linked to a signified) is a phonogram – that is, a 'sound' (*phono*) 'character' (*gram*). Examples are the hieroglyph 𓂋 depicting a mouth and denoting the sound *r*, 𓅓 depicting an owl and denoting the sound *m*, and 𓅱 depicting a swallow and denoting the two sounds *w* + *r*. Phonograms represent one, two, or three consonants and are hence called uniliteral, biliteral, and triliteral, respectively. Vowels are not written. Phonograms often serve as phonographic complements. For example, 𓂋 *r* is a complement in 𓅱 *wr* (*wr* + *r* = *wr*).

The Rebus Principle

How can pictures denote sound? Sounds are derived from pictures by means of the rebus principle. *Rebus* is Latin for '(to represent sounds) by (depicting) objects.' In English, one might playfully represent the pronoun 'I' by an eye (𓁹). In hieroglyphic writing, many phonograms are derived from pictures in this way. For example, *r* 'mouth' is written with the ideogram 𓂋 depicting a mouth. In rebus writing, 𓂋 turns into a phonogram representing the sound *r* in any word. Technically, the following happens: 𓂋 originally denotes the mouth as a signified. This signified is linked to the signifier, the sound *r*. Through the sign link, 𓂋 secondarily also denotes the sound *r*. In rebus derivation, a hieroglyph originally denoting a signified as an ideogram and therefore secondarily also the signifier attached to this signified is cut loose from the original signified and left to express only the signifier as a phonogram.

The 'Alphabet'

Like any language, Egyptian consists of a limited set of distinctive sounds, phonemes. Each consonant phoneme, 25 or so in number, can be represented by its own phonogram. The whole set is called the alphabet. Hieroglyphic writing is not purely alphabetic, however. Other signs are used alongside the alphabetic phonograms. Still, the alphabet accounts for approximately half of the signs in any text.

Asymmetry of Ideograms and Phonograms: The Logogram

Ideograms and phonograms exhibit a most characteristic asymmetry. Ideograms always denote sound in addition to meaning. Phonograms only sometimes denote meaning in addition to sound. Accordingly, ideograms are always logograms, whereas phonograms are only sometimes logograms. Because signified and signifier are linked in the sign, ideograms also denote sound. Thus, the ideogram 𓁷 in 𓁶 'head' conjures up not only the head as a signified but also the sounds *tp* as a signifier. In referring to both sides of a word, directly to its signified and indirectly to its signifier, ideograms are also always logograms, 'word' (*logo*) 'characters' (*gram*). On the other hand, only a full sound pattern as signifier is linked to a signified. Therefore, only phonograms denoting a full sound pattern are also logograms. For example, 𓅓 in *m* 'in, from' is both a phonogram and a logogram. It denotes every consonant of the word in question. However, the phonogram 𓅓 is not a logogram in 𓅓 *mr* 'director.' It denotes only one of the sound pattern's two consonants.

The Determinative

In addition to the ideogram and the phonogram, the determinative is a third type of hieroglyph. Determinatives appear at the ends of words and determine the meaning class to which a word belongs. Determinatives refer to a property of signifiers, namely their class appurtenance. Thus, words denoting human beings often end in 𓀀, a seated person. Words denoting time often end in 𓇳, the sun. Plurals mostly end in 𓏺, the so-called plural strokes.

Hieroglyphs often function in two or more capacities. 𓉐 functions as an ideogram in 𓉐 *pr* 'house,' as a phonogram in 𓉐𓄿 *pr*(*y*) 'go out' (𓄿 being a determinative in verbs denoting motion and *y* a 'weak' consonant mostly left unwritten), and as a determinative in many words denoting buildings. Ideogram, phonogram, and determinative are therefore types of hieroglyphic functions rather than types of hieroglyphs. Words are written in many various combinations of one or more of the three types (ideogram, phonogram, and determinative) and contain one to five or six hieroglyphs, sometimes more.

Types: Hieroglyphic Proper, Cursive Hieroglyphs, Hieratic and Demotic

Hieroglyphs normally exhibit their full pictorial quality only when chiseled or painted. This is hieroglyphic writing proper. When writing with a pen on papyrus, scribes used cursive variants. Pen-written hieroglyphs are called hieratic, which is Greek for 'priestly (script).' The distinction between 'hieroglyphic' and 'hieratic' appears first in Clement of Alexandria (200 C.E.). Hieratic was by then used mainly in papyri inscribed by priest-scribes with religious texts.

Earlier, however, in the 3rd and 2nd millennium B.C.E., hieratic was used for all pen-written texts composed in the first three stages of the language – Old, Middle, and Late Egyptian. 'Hieratic' in its modern use is therefore a misnomer. A type of writing less cursive than hieratic is cursive hieroglyphs, used typically in Book of the Dead papyri, whose earliest specimens date to approximately 1500 B.C.E.

From the 7th century B.C.E. onward, an extremely cursivized variant of hieroglyphic writing, called demotic, is attested for more than a millennium. It is used to write the fourth stage of the language, also called demotic. Demotic means '(script) of the people.' The name first appears in Herodotus (5th century B.C.E.). Hieroglyphic proper and hieratic had by then become limited mainly to monumental and religious texts. A most typical trait of demotic is that the hieroglyphs of a word often merge into a single composite sign that takes on a life of its own. Many demotic words are therefore written with their very own sign. Demotic consequently makes great demands on an ancient scribe's or modern scholar's paleographic memory.

Varia

There are additional distinctive properties of hieroglyphic writing worthy of note. First, hieroglyphic writing as a rule runs from right to left, with people and animals depicted in hieroglyphs facing right. Texts are mostly written in lines. However, columns were always common in monumental arrangements. They were also the norm early on in hieratic, in the 3rd millennium B.C.E.

Second, two types of restricted use are syllabic writing, used to write Semitic words in the New Kingdom (second half of the 2nd millennium B.C.E.), and Ptolemaic writing, which is attested mainly in temple inscriptions from approximately 300 B.C.E. onward and in which the conventions of writing are stretched to include many new signs and new values that are often cryptic or playful.

Third, in terms of number, A. H. Gardiner's sign list in *Egyptian Grammar*, still the most authoritative, contains fewer than 800 signs. However, the number of those used frequently is less. In Ptolemaic writing, the sign inventory runs into the thousands.

Fourth, late period pseudo-explanations indicate dwindling knowledge of hieroglyphic writing. In his book on hieroglyphs, Horapollo (5th century C.E.) knows that the hieroglyph 𓃹, a hare, is used to write the word meaning 'to open.' However, he falsely assumes that that is because hares always keep their eyes open. Rather, 𓃹 is a biliteral phonogram. It denotes the consonants $w + n$, as in *wn* 'to open.' It is a rebus derivation from the ideogram 𓃹 appearing in *wn* 'hare.'

Albert Einstein was born on March 14, 1879, at Ulm, in Württemberg, Germany, and died April 18, 1955 in Princeton, New Jersey. After starting out at the Luitpold Gymnasium in Munich, he forfeited his German citizenship in 1896. In 1901, he graduated from the Swiss Federal Polytechnic School in Zurich and obtained Swiss citizenship. Unable to find a teaching post, he took a job at the Swiss patent office and continued his work in physics. In 1905, he earned a doctorate from the University of Zurich and by 1911 was full professor at the Karl-Ferdinand University in Prague. In 1912, he moved to a chair at the Zurich Eidgenössische Technische Hochschule. In 1921, he received the Nobel Prize for his paper on the photoelectric effect and also the Barnard Medal. That year he raised funds for the Hebrew University in Jerusalem. In 1925, he was awarded the Copley Medal of the Royal Society and in 1926 the Gold Medal of the Royal Astronomical Society. In 1932, he moved to Princeton University, and after the Nazis came to power never returned to Germany.

Einstein's special theory of relativity, pertaining to inertial motions, was linked to the surprising discovery that the speed of light is evidently invariant irrespective of the velocity of objects emitting it. His general theory of relativity, accounting also for acceleration, though still regarded as controversial remains the most unifying conception in physics. His search for a unified field theory, however, was unsuccessful. In addition to his work in physics, Einstein anticipated certain developments in modern linguistics and the philosophy of language, for which he has received little notice. For instance, in a 1941 radio talk entitled 'The common language of science,' he anticipated by more than two and a half decades Chomsky's (1965) observation that certain grammatical rules must be known by 'intuition' in order for languages to be acquired. Einstein wrote, "If language is to lead at all to understanding, there must be rules concerning the relations between the signs on the one hand and on the other hand there must be a stable correspondence between signs and impressions. In their childhood individuals connected by the same language grasp these rules and relations mainly by intuition" (Einstein, 1941/1956: 209). In fact, Einstein carried the conception of grammar all the way to its modern pragmatic phase.

Einstein capsulized P. F. Strawson's modification of the correspondence theory of truth and, independently, voiced much the same criticism of Bertrand Russell's thinking. In particular, Einstein insisted that "everything depends on the degree to which words and word-combinations correspond to the world of impression" (Einstein, 1941/1956: 110). He did not elevate raw facts, however, to the position of determining propositional syntax as the logical positivists were prone to do, nor did he commit the error of situational semantics where raw facts are accorded distinct identities without the assistance of propositions to single them out. Although it is doubtful that he ever met C. S. Peirce, it seems that Einstein was indirectly influenced by Peirce's followers, especially John Dewey, and possibly by Jean Piaget who held certain ideas in common with Dewey. Einstein was a rational empiricist, however. Although he accorded reality to observers, material objects, and events, he insisted that propositional representations must remain free of any deterministic control by the material world. Oddly, in his search for a unified field theory he had to suppose that the slightest motion of any material body (including living bodies) must be subject to strictly deterministic physical laws. Had his hope for such a theory panned out, it would have removed all stochastic processes and events. Einstein capsulized this expectation in a statement eagerly quoted by biographers: "I refuse to believe that God plays dice with the universe" (Clark, 1971: 742).

Nonetheless, with respect to language Einstein argued for free will and, anticipated arguments for Chomskyan linguistic creativity. This was made plain in Einstein's argument with Bertrand Russell where he insisted that "the concepts which arise in our thought and in our linguistic expressions are all – when viewed logically – the free creations of thought which cannot inductively be gained from sense experiences . . . . we do not become conscious of the gulf – logically unbridgeable – which separates the world of sensory experiences from the world of concepts and propositions" (Einstein, 1944: 297). Here, Einstein anticipated Chomsky's argument for the relative autonomy and freedom of grammar contra B. F. Skinner. However, Einstein reached further to argue for a conception of grammar that attaches bodily objects, persons, and real events to referring terms. It has become increasingly evident that this sort of pragmatic mapping is necessary if we are to explain child language acquisition and successful communications that depend on language (Oller *et al.*, 2005).

The following list includes the works cited here and a selection of Einstein's most relevant and accessible writings that deal directly or indirectly with language and linguistics.

18th Century Linguistic Thought

G Haßler, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

The 18th century has been characterized as a century of debate on language, leading to the formation of new conceptions in this field. The focus on language has also been supported by the role of public opinion and by profound changes in society. But the most important discussions were about the role of language in thought. In the field of language description, 18th-century authors followed for the most part traditional views and contributed to their further development.

Discussions on Language in the Early 18th Century

The inclusion of language in the philosophical systems of Rene Descartes (1596–1650), Antoine Arnauld (1612–1694), and Baruch de Spinoza (1632–1677) was based on the supposition that there was an analogy between the dualism of language and thought and that of body and mind. The basis of the doctrine, which supposed an incorporeal thinking no longer accessible to humans after original sin, had already been developed by St Augustine (354–430). From a historical perspective, thinking required signs to render collections of simple ideas, as well as memory, possible. Signs gave rise to the manipulation of ideas, and they did not depend on the presence of things or the enumeration of all the simple ideas included in them.

A main tenet of the Augustinian–rationalist doctrine was the merely spiritual nature of all notions and of the relations between them. The denotation of a term was regarded as a mental object that could only have a representational relation to the word and could not depend on linguistic signs and their corporeal nature. The form words obtained in different languages was regarded as arbitrary, whereas the composition of the concept was universal and did not depend on sensations. For the rationalist thinkers, the indispensability of language consisted only in communication between people when the transmission of pure incorporeal notions was impossible. But linguistic signs met the necessities of communication in a very insufficient way because intuitive conceptions overwhelmed the human mind while their linguistic signs distracted from their content and slowed down the process of thinking.

Descartes's vision of the relation between language and thought was a dualistic one, in that he did not attribute to linguistic signs any influence on ideas. He saw a confirmation of this opinion in the fact that animals with highly developed speech organs did not develop human thinking even if they were able to produce some speech sounds. This idea was further developed by Gerauld de Cordemoy (1626–1684), who claimed that the substantial difference between language and thought allowed the development of different languages with arbitrary sound patterns.

The authors of the Port-Royal Grammar (1660) and the Logic (1662) took up the distinction between language-independent thought, communicated thought, and language-dependent thinking, and they subordinated linguistic signs to conceptual notions. Had ideas depended on names, people would not have had the same ideas about even the simplest things

languages were equal in rank and could not be reduced to a universal grammar, Jenisch envisaged an impartial comparison of languages. But his idea of empiricism was merely hypothetical and based on literature.

So the prize-winning topic on the comparison of languages did not prepare or even open a new epoch of language studies but concluded the discussion on universals and the relativity of languages in the context of the Enlightenment debate. At the end of the 18th century, new kinds of empirical questions were emerging, but many authors still tried to address them through the old epistemological framework.

El Salvador: Language Situation

J DeChicchis, Kwansei Gakuin University, Sanda, Japan

© 2006 J DeChicchis. Published by Elsevier Ltd. All rights reserved.

The República de El Salvador is linguistically more Spanish than Spain. Nine tenths of this Spanish-speaking Central American culture is ethnically mestizo (of mixed American and European heritage). Almost none of the resident Amerindians can speak anything but Spanish, which is also the dominant language of most of the European Salvadoreños. Other languages are spoken primarily as foreign languages of cultural and commercial interaction, with the possible exception of some Mayan-speaking immigrants from Guatemala. Spanish usage is so strong that, although knowledge of English is widespread in San Salvador business circles, even foreigners

in El Salvador tend to use Spanish, perhaps because there is a relatively small non-Hispanic foreign population.

Salvadoran Spanish resembles Honduran and Nicaraguan Spanish, yet it is in some ways closer to the general pan-American pattern, perhaps as a result of El Salvador's greater urbanization and high population density. The greatest differences can be seen among the farmers and the landed gentry, whereas the speech of the urban middle class is more similar to that of their counterparts in Honduras, Nicaragua, and even Guatemala. Vocabulary items typical of Salvadoran Spanish have been listed by the Real Academia de la Lengua Española. Widespread is the use of *pal* for *para* and the use of *chontoca* for *cabeza*. The Salvadoran scholar P. Geoffroy Rivas has suggested Amerindian language sources for much of the local vocabulary, and his book *La lengua salvadoreña* (1969) is the most widely cited authority; however, a truly thorough lexicography has yet to be written. Whatever the etymologies may be, young business professionals have been spreading their emblematic vocabulary, the 'salvadoreñismos,' throughout Central America and even beyond.

Despite their continued existence as identifiable ethnic groups, the Lenca and the Pipil have effectively ceased speaking their languages. Lenca has not been definitively classified, though a Macro-Chibchan affiliation is commonly assumed. The Pipil language, which is locally known as Náhuat (Nahuate, Naawat, Nawaa), is an Uto-Aztecan language. Although a government commission was formed in 1980 to save this language, Náhuat is now nearly extinct. It is possible that the archival speakers of these languages, preserved in audio and audiovisual recordings, may one day spark language revivals, although this seems highly unlikely for Lenca. Token speakers of Náhuat can be found in Sonsonate, Ahuachapán, La Libertad, and Santa Ana, and there are token speakers of Lenca in La Unión; however, neither Náhuat nor Lenca is a colloquial language of daily communication in El Salvador.

More than twelve thousand Q'eqchi' (Kekchí) speakers are widely reported to live in El Salvador, but this seems false, though the source of this error is unclear. Any Q'eqchi' living in El Salvador are certainly recent immigrants from Guatemala, and migration studies have identified no large population of Q'eqchi' in El Salvador, suggesting instead that there are actually many more Q'eqchi' speakers living in the United States. Occasional reports of Chortí speakers in El Salvador are also false, an error likely due to careless 'ruta Maya' tour promotion. Despite their historical presence, there is currently no Mayan speech community in El Salvador.

Elamite

G B Gragg, University of Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Elamite was a language spoken on the Iranian plateau from at least the end of the fourth millennium B.C.E. until at least the end of the Persian Empire in the fourth century B.C.E. It is attested in thousands of cuneiform documents, the great majority of which come from the western and southwestern periphery of that area, in the modern provinces of Khuzestān and Fārs, especially from the sites of Susa, which was an important political and economic center during the whole period, and Persepolis, the dynastic center of the Achaemenid Empire. The Elamite texts are almost exclusively either monumental (e.g., building inscriptions) or administrative (e.g., accounts, rations) in character. Elamite was first identified by European scholarship early in the 19th century because of its inclusion in many of the Achaemenid bilingual and trilingual monumental inscriptions: Old Persian, written in a specially created alphabetic script, and Akkadian (Babylonian) and Elamite, both written in Mesopotamian cuneiform. This corpus

in El Salvador tend to use Spanish, perhaps because there is a relatively small non-Hispanic foreign population.

Elamite

G B Gragg, University of Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Elamite was a language spoken on the Iranian plateau from at least the end of the fourth millennium B.C.E. until at least the end of the Persian Empire in the fourth century B.C.E. It is attested in thousands of cuneiform documents, the great majority of which come from the western and southwestern periphery of that area, in the modern provinces of Khuzestān and Fārs, especially from the sites of Susa, which was an important political and economic center during the whole period, and Persepolis, the dynastic center of the Achaemenid Empire. The Elamite texts are almost exclusively either monumental (e.g., building inscriptions) or administrative (e.g., accounts, rations) in character. Elamite was first identified by European scholarship early in the 19th century because of its inclusion in many of the Achaemenid bilingual and trilingual monumental inscriptions: Old Persian, written in a specially created alphabetic script, and Akkadian (Babylonian) and Elamite, both written in Mesopotamian cuneiform. This corpus

provided the basis for the decipherment of Akkadian, and hence Elamite, cuneiform in the 1840s.

The earliest evidence of texts in the region was found on about 1500 clay tablets dating from about the end of the fourth and beginning of the third millennium B.C.E. They are written in a still undeciphered script termed, misleadingly, 'Proto-Elamite.' The language of these texts is presumed, but not proven, to be Elamite. The same can be said about another small corpus of about 20 texts from the end of the third millennium written in an indigenous but cuneiform-like script known as 'Linear Elamite.' Apart from these two very early corpora, Elamite texts are written in various local adaptations of Mesopotamian cuneiform, usually with a significant reduction in the number of syllabic and logographic values and the occasional creation of a new local value. This corpus of texts is unevenly distributed over the commonly recognized periods given in Table 1. Achaemenid Elamite is obviously the best attested and most studied of these corpora, but, in part because of the massive presence of Old Persian and other Iranian names and loanwords in this period and doubts about the extent of Iranian influence on the development of the Elamite language, Middle Elamite, where it differs from Achaemenid Elamite, tends to be taken as a kind of classical norm.

Elamite cannot with any certainty be related to any known language, although a geographically plausible relation to the Dravidian languages has been discussed almost since the beginning of modern scholarship in the language (see the synthesis of McAlpin, 1981). Partly because of the lack of a known cognate language and partly also because of the relatively limited and stereotyped nature of the contents of the corpus, the interpretation of many aspects of Elamite grammar remains uncertain and subject to a great deal of discussion in the literature.

Table 1 Periodization of Elamite

Period B.C.E.	*Designation*	*Texts*
c. 2600–1500	Old Elamite	Less than a dozen texts of varied content
c. 1500–1000	Middle Elamite	Almost 200 royal monumental inscriptions
c. 1000–550	Neo-Elamite	About 30 royal inscriptions and several hundred legal and administrative texts
550–330	Achaemenid Elamite	The several hundred royal inscriptions and several thousand administrative texts from the administrative centers of the Persian Empire

In terms of word-order typology, Elamite has predominantly subject-first, verb-last order, with a certain amount of variability. Adjectival, genetival, and relative modifiers normally follow the head noun; adverbial relations are rendered principally by postpositions, although there are also some prepositions. It is a subject of current debate whether Elamite displays features that might be termed 'ergative,' but in any case it is much less so than its contemporary neighbors Hurrian, Urartian, and Sumerian. Elamite morphology is almost exclusively suffixing. A central role in morphology and syntax is played by a classifier suffix/enclitic, NCLASS, marking person, number, and various classes of animacy and inanimacy. This formative plays the role of subject marker in two of the three verb conjugations, but it is also used in one of most characteristic features in the language: the delineating of a syntactic constituent N_{HEAD} adjunct by one or more occurrences of a NCLASS agreeing with the head. The adjunct can be an adjective or a possessor, as in:

(1) temti riša-r
lord.ANIM.SING great-NCLASS.ANIM.SING
'great lord'

(2) ulhi sunki-me
house.INAN.SING king-NCLASS.INAN.SING
'house of the king'

or in some more complex combination of the two:

(3) sian Nabu-me upat-hussi-p-me kuši-h
temple.INAN.SING Nabu-NCLASS.INAN.SING
brick.AN.PL-baked-NCLASS.AN.PL-NCLASS.INAN.SING
build-I
'I built a Nabu temple of baked brick'

The adjunct can also be used as relative (note the additional NCLASS formative after the negation marker before the relativized verb):

(4) sian in-me kuši-h-š-me-a
temple.INAN.SING not-NCLASS.INAN.SING build-PL-
3RD-NCLASS-COMP
'the temple which they did not build'

Finally, this marking can occur even in sequences which, for example, in English, would not normally be treated as a syntactic constituent (on this construction see Stolper, 2004: 85):

(5) peti-p pat-p u-p rabba-k-na
enemy.AN.PL-NCLASS[AN,PL] under-NCLASS.AN.PL me-
NCLASS.AN.PL bind-PERF-OPT
'may enemies be bound under me'

The last example illustrates that the NCLASS can also occur on the head noun, in this case explicitly marking it as plural.

Electrical Stimulation of Cortex and Language

S C Bhatnagar, Marquette University, Milwaukee, WI, USA

G T Mandybur, University of Cincinnati, Cincinnati, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The use of the focal external electric stimulation technique intraoperatively is based on early observations of Fritsch and Hitzig (1870) and Bartholow (1874); they noted that an externally applied electric current to the exposed brain evokes sensorimotor experiences. Cushing (1909) was the first to use the focal external current to map out the somatosensory cortex in humans. With safety and reliability established over the past 50 years, this technique of stimulation has become a standard part of neurosurgical treatment for intractable epilepsy, tumour removal and for the management of the arteriovenous malformations. The goal of the stimulation technique is to determine the extent of tissue resection while preserving sensorimotor and critical cortical language and memory functions (Penfield and Roberts, 1959; Ojemann, 1983, 1993). In surgical management of seizure, the focal external current is used first to define the epileptogenetic region and second to map out the cortical sites serving memory and language functions. This functional mapping plays a crucial role in determining the extent of tissue resection, particularly from the left perisylvian region, since any tissue removal from the tempoparietal cortex can result in a permanent language deficit (Bhatnagar *et al*., 2000; Ojemann, 1983, 1993; Penfield and Roberts, 1959).

Focal Electric Brain Stimulation Technique

The intraoperative stimulation technique involves craniotomy and functional mapping of the exposed cortex. Since a patient's active participation is essential for any mapping of neurolinguistic functions, the intraoperative stimulation of the brain tissue is performed on patients who are awake. Minimal anesthesia is used with intravenous propofol and local anesthetics. Advances in technology have also allowed extraoperative stimulation mapping using subdurally implanted grids with multiple electrodes. The two issues closely related to stimulation mapping of the brain are stimulation parameters used for localizing functions and selection of linguistic tasks for measuring language. The electrophysiologic rule governing the parameters of stimulating current is that the selected current strength should be great enough to interfere with language processing, but it should be lower than the current trains that cause any after-discharges and/or trigger seizure activity. Therefore, the stimulation thresholds used for mapping an area are carefully selected to avoid after-discharges and are above the thresholds for sensorimotor responses. The external focal electric stimulation is applied using bipolar (sometimes unipolar) electrodes through a hand-held constant current generator, which generates a biphasic square waveform of pulse and ensures proper protection for the tissue. The electrodes are made of platinum or a combination of other materials to avoid polarization and vary in size from 0.5 to 3.00 mm in diameter with a center-to-center interelectrode distance of 0.5 to 2 mm. The stimulation involves a current strength ranging from 0.5 to 15 mA with

Electrical Stimulation of Cortex and Language

Introduction

The use of the focal external electric stimulation technique intraoperatively is based on early observations of Fritsch and Hitzig (1870) and Bartholow (1874); they noted that an externally applied electric current to the exposed brain evokes sensorimotor experiences. Cushing (1909) was the first to use the focal external current to map out the somatosensory cortex in humans. With safety and reliability established over the past 50 years, this technique of stimulation has become a standard part of neurosurgical treatment for intractable epilepsy, tumour removal and for the management of the arteriovenous malformations. The goal of the stimulation technique is to determine the extent of tissue resection while preserving sensorimotor and critical cortical language and memory functions (Penfield and Roberts, 1959; Ojemann, 1983, 1993). In surgical management of seizure, the focal external current is used first to define the epileptogenetic region and second to map out the cortical sites serving memory and language functions. This functional mapping plays a crucial role in determining the extent of tissue resection, particularly from the left perisylvian region, since any tissue removal from the tempoparietal cortex can result in a permanent language deficit (Bhatnagar *et al*., 2000; Ojemann, 1983, 1993; Penfield and Roberts, 1959).

Focal Electric Brain Stimulation Technique

The intraoperative stimulation technique involves craniotomy and functional mapping of the exposed cortex. Since a patient's active participation is essential for any mapping of neurolinguistic functions, the intraoperative stimulation of the brain tissue is performed on patients who are awake. Minimal anesthesia is used with intravenous propofol and local anesthetics. Advances in technology have also allowed extraoperative stimulation mapping using subdurally implanted grids with multiple electrodes. The two issues closely related to stimulation mapping of the brain are stimulation parameters used for localizing functions and selection of linguistic tasks for measuring language. The electrophysiologic rule governing the parameters of stimulating current is that the selected current strength should be great enough to interfere with language processing, but it should be lower than the current trains that cause any after-discharges and/or trigger seizure activity. Therefore, the stimulation thresholds used for mapping an area are carefully selected to avoid after-discharges and are above the thresholds for sensorimotor responses. The external focal electric stimulation is applied using bipolar (sometimes unipolar) electrodes through a hand-held constant current generator, which generates a biphasic square waveform of pulse and ensures proper protection for the tissue. The electrodes are made of platinum or a combination of other materials to avoid polarization and vary in size from 0.5 to 3.00 mm in diameter with a center-to-center interelectrode distance of 0.5 to 2 mm. The stimulation involves a current strength ranging from 0.5 to 15 mA with

biphasic square wave pulses, each of 0.3 to 1 ms at the rate of 50 to 60 Hz for a duration of 2 to 8 s. Functional disruptions in the brain by stimulation would have no value if the applied currents can trigger afterdischarges; this would not only negate the observed local functions but would also indicate a spread of the current volleys along the en-passage fibers. The stimulation serves as a reversible transient lesion and its effect rarely lasts longer than the stimulation duration. The stimulating current is applied at some point when the patient is performing a language task. This performance is called the stimulation (experimental) trial and it is mixed with nonstimulation (controlled) trials. The patient's performance is statistically examined to ensure that the stimulation-evoked positive responses of language errors are not random events. An interesting observation about the focal electric stimulation is that the current below threshold for seizure discharges evokes positive responses from the sensorimotor cortex. However, the application of this current, when applied to other brain areas, including the association cortex outside the sensorimotor region in awake patients, did not evoke any spontaneous verbal response. Penfield and Roberts (1959) noted that the application of the same current in some region of the association cortex can block an ongoing linguistic activity in an awake patient. This physiologic effect is based on the interference that the focal stimulation produces during the linguistic task. If stimulation at a cortical site disrupts (positive response) ongoing naming/speaking, the cortical area in question is considered to be functional for the task. If the stimulation does not block or alter the naming/speaking process, the stimulated area is not considered to be involved in language (see **Figure 1**).

The language task that has commonly been used to measure language during functional mapping of the brain is naming, which involves asking the subject to name pictured objects. The rationale for considering naming to reflect a measure of language during stimulation mapping has been the presence of the word-finding disorder in all types of aphasias in neurological patients.

As a technique, stimulation mapping has proven to have a significant advantage over lesion evidence since each subject serves as his or her own control. The patient's performance during nonstimulation trials serves as a controlled trial and it can be compared with the performance during stimulation to evaluate the reliability of evoked errors. Further, stimulation-induced interruptions provide precise details about functional localization, since the extent of the transient lesion can be only several millimeters in diameter, ranging from 0.5 to 3.00 mm. The stimulation is not known to leave any lingering effect and/or postoperative aphasia. Carefully controlled stimulation parameters pose no safety concern to patients, cause no injury to the examined brain tissue, and produce no evidence of acute inflammation to the mapped

Figure 1 An exposed human brain during electrocorticography prior to determining the extent of tissue removal. Numbered tickets mark sites that have been functionally mapped during intraoperative neurolinguistic testing. Many of the numbered sites were implicated in language and/or memory functions. region of the brain (Ojemann, 1993). Furthermore, the effects of the stimulation on a particular site are repeatable but at times qualitatively different from other evoked changes from the same site as well as the sites in near proximity. Multiple samples of one or more linguistic behaviors from a single site allows us to evaluate the role that the tissue in question plays in language processing. Examination of the postoperative impact of tissue resection from the language-specific area has revealed that if the tissue resection site is 2 cm away from a cortical site implicated in language in the temporal lobe, no postoperative aphasia will be observed. On the other hand, a word-finding deficit has been noted to be present if the tissue removal comes within 2 cm from the site implicated in language (Ojemann, 1983; Ojemann and Dodrill, 1987).

A notable limitation of the focal cortical stimulation technique for functional mapping of the brain is the time constraint imposed by the surgery. This limitation, however, has been lessened because of technical advances involving the subdural implantation of a flexible grid with multiple electrodes on the cortical surface. The grids containing multiple electrodes can be left in the brain for varying time periods ranging from days to weeks after, thus allowing for neurolinguistic testing when the patient is rested, out of the surgery, and in a more natural environment (Uematsu *et al.*, 1992; Lesser *et al.*, 1981, 1984, 1994; Morris *et al.*, 1984).

Neurolinguistic Studies Using Stimulation Mapping

Over the past 50 years, focal cortical stimulation has been used for exploring neurolinguistic properties of the human brain. In light of the length limitations of this work, only a few significant neurolinguistic investigations will be discussed. The earliest series of investigations of cortical mapping of language function was undertaken at the Montreal Neurological Institute by Wilder Penfield and his colleagues (Penfield and Roberts, 1959; Penfield and Jasper, 1954), who functionally mapped the brains of approximately 110 neurosurgical, mostly epileptic, patients. Using naming and its evoked errors (misnaming and omission) as a measure of language, they reported approximately 132 aphasic-like errors, a very small number from a total of 110 patients (Ojemann and Whitaker, 1978). Penfield and his colleagues not only identified a large area essential for language in the left fronto–parieto–temporal cortex, but also explored the cortical regions that served motor speech, memory, and psychical (emotional) responses that consisted of hallucinations and interpretative illusions.

Using naming again as a measure of language, Fedio and Van Buren (1974) observed the evoked anomic errors from a large region of the fronto–parieto–temporal cortex; this area appeared to be larger than the area previously implicated in language. Searching for the correlates of verbal memory, Fedio and Van Buren noted that the stimulation of the posterior temporal–parietal cortex resulted in an impaired ability to recall stored verbal information, whereas the stimulation of the anterior temporal lobe interfered with the registration of new learning. In a series of neurolinguistic investigations using naming and a few other linguistic stimuli, Ojemann and colleagues noted a discrete localization of language in the human lateral cortex (Ojemann and Whitaker, 1978; Ojemann, 1983, 1993). Each of the mapped areas was found differentially committed to language in 50–80% of the patients sampled with the exception of a narrow region of the posterior–frontal lobe, which was implicated in all patients. This region appeared to be the most essential for language. Incidentally, this region of the posterior–frontal lobe is only a small part of the frontal language cortex.

Other significant neurolinguistic observations of stimulation mapping are as follows: (1) there was a differential organization of primary and secondary languages in the brains of bilingual subjects (Ojemann and Whitaker, 1978); (2) the cortical areas related and unrelated to language were separated by a boundary that was gradual (Whitaker and Ojemann, 1977); (3) cortical areas serving language, measured by object naming, were separate but were located adjacent to the areas that had been implicated in short-term verbal memory during stimulation (Ojemann, 1993); (4) cortical areas related to mimicry of sequential movements were also associated with phonemic identification (Ojemann and Mateer, 1979); and (5) many of the sites involved in object naming were implicated in syntactic errors in oral reading (Ojemann, 1983). This wealth of data supports an overlapping of cortical areas serving language, speech, verbal memory, and motor sequencing, which in turn contradicts the classical lesion-based application of discrete functional localization. Additional evidence exists to suggest that neurolinguistic representation of the human brain is possibly columnar or multilayered. Stimulation-based mapping of the brain examining semantic and syntactic tasks involved in the formulation of structurally intact sentences did not support the dichotomized discrete representation for syntax and semantics in the human brain (Bhatnagar *et al.*, 2000). The functional mapping of the brain confirmed that a large part of the fronto–parieto–temporal cortex in the left brain is involved in language as

measured by object naming only. A few of these sites throughout the entire fronto–parieto–temporal cortex were also implicated in syntactic morphology. However, only very few of the cortical sites from the inferior parietal region, or from the posterior and anterior temporal regions, participated in the semantic processes involved in sentence formation. This multitiered representation of language (naming, syntactic morphology, and semantic) functions implicating variable contributions of brain tissue to the overlapped – diffused and/or discrete – multiple functions supports a powerful and optimal model of the human brain, where language as a mental phenomenon evolves through qualitatively different forms within the same cortical tissues (Bhatnagar *et al.*, 2000). Emergence of different language errors from the same sites reveals a progressive unfolding of mental representation in logical time though not necessarily in the microseconds of real time and is reminiscent of the microgenesis model of Jason Brown (1988).

Neurolinguistic Studies Using Subdural Electrodes

A significant limitation of cortical mapping during craniotomy was the time that restricted language testing to less than 1 h (Lesser *et al.*, 1994; Umetsu *et al.*, 1992). A clinically driven need for better stimulation has led to the implantation of multiple electrodes using subdural grids and strips (see Figure 2). Common grid patterns that are used include arrays consisting of 8×8, 6×8, and 2×8 electrode arrangement and stripes containing 1×8 or 1×4 electrodes. They can be placed either under general or local anesthesia using standard neurosurgical procedures (Lesser, 1984). The stimulating current intensity using standard parameters is gradually increased until the current results in a functional interruption, or triggers after-discharges, or reaches the intensity limit of 15–17 mA (Gordon *et al.*, 1990; Lesser *et al.*, 1987). Other advantages of the subdural implantation include covering a better and larger area of the brain using multiple electrodes and far fewer artifacts to contaminate the results. The procedure involves using electrodes in a bipolar fashion incorporating two adjacent electrodes. If a pair of electrodes is found to be active, then one of the active electrodes is paired with other adjacent electrodes to determine whether one could localize the responsible electrode site with precision. An advantage of a subdural grid is that it allows for the localization of epileptogenetic areas and the identification of cortex involved in language, unhampered by the time restrictions in the intraoperative experimental procedural condition. This arrangement also permits an in-depth evaluation of language where the investigator can further question the patients about the awareness of the processes underlying the evoked linguistic errors. Neurolinguistic observations obtained from the patients

Figure 2 An exposed human brain during electrocorticography with an illustration of a subdural electrode grid placement in the management of seizure. Courtesy of Drs. Ronald P Lesser and Barry Gordon, Department of Neurology, The Johns Hopkins Medical Institutions.

with subdural grids of electrodes were similar to observations obtained from the stimulation using a hand-held stimulator. Other significant observations included the evoked dissociation of naming from reading (Lesser *et al.*, 1987) and the fractionation of the components of Gerstmann's syndrome from the stimulation of different sites within the angular gyrus (Morris *et al.*, 1984).

Stimulation of Subcortical Structures

Stereotaxic intervention, a precise method of identifying and targeting subcortical anatomic structures by use of three-dimensional coordinates for tissue destruction, has long been used in neurosurgery for treating movement disorders, postural abnormalities, and intractable pain. Clinical needs for safer and more effective treatment have replaced tissue destruction with stimulation using depth electrodes implanted stereotaxically in thalamic nuclei and basal ganglia structures (see Figure 3). Subcortical structures of the brain that have been targeted during neurosurgical procedures and examined for their role in higher mental function include the ventral lateral (VL) and centromedianum (CM), two most investigated nuclei of the thalamus and the basal ganglia structures of the posterior ventral pallidum (PVP) and subthalamic nucleus (STN). Other, though less frequently investigated structures include the cingulate, peri acqueductal gray, anterior and medial thalamus, and the subthalamic region.

Language generation in humans is a vastly complex event. It has been considered exclusively a cortical function implicating dominant temporal–parietal and frontal areas. However, the complexity of language and the cognitive processes underlying the use of language functions would strongly implicate much more than merely cortical structure. Surgically based neurocognitive studies have revealed that the generation of language also involves subcortical structures including the lateral basal ganglia, thalamus, and associated structures, creating a cortico–subcortical–cortical linguistic loop.

Role of Thalamus in Language Functions

Ventrolateral Nucleus Laterality of language extends even to the subcortical level. Notable differences in effect are seen when the dominant thalamus vs. the nondominant thalamus is stimulated. Aphasic manifestations have been documented after left thalamic involvement but are not seen after right thalamic perturbation. Originally, support for a thalamic role in the processing of language came from cases with hemorrhagic strokes or tumors involving the dominant VL nucleus, resulting in an array of disorders from motor speech (dysarthria) to language (anomia, paraphasia, and jargon verbal output). For example, subjects with left thalamic infarcts have been known to produce fluent verbal output characterized by jargon, anomia, and verbal paraphasia (Alexender and Lo Verme, 1980).

Further support of a thalamic role in language comes from stereotactic procedures, where selective therapeutic lesions placed in the left VL thalamus have resulted in linguistic impairments such as the following: reduced loudness, impaired motor quality of speech (dysarthria), anomia (Bell, 1968), arrests of speech (Guiot *et al.*, 1961), and word-finding errors (Ojemann, 1983; Selby, 1967; Vilkki and Laitinen, 1976; Fedio and Van Buren, 1975). Evoked errors in naming were also observed from stimulation of the

Figure 3 (A) Deep brain stimulator electrode unit (lead) and implantable programmable neurostimulator generator. (B) Diagrammatic representation of a deep brain stimulator implanted in the human brain. Courtesy of Medtronic Corp., Minneapolis, MN.

central medial part of the left VL nucleus and perseveration of the first syllable during left VL nucleus stimulation (Ojemann *et al.*, 1971).

The pulvinar has also been implicated in language functions, where its stimulation resulted in the impaired ability to name with preserved speaking ability (Ojemann *et al.*, 1968).

Neurosurgical investigations have also implicated the left thalamus with verbal memory; the electrical stimulation of the left VL nucleus produced a facilitatory impact on object naming and lexical memory, depending on the processing phase when the stimulation was delivered. This facilitatory effect has been referred to as the 'specific alerting response' (Ojemann, 1983). This alerting mechanism also rendered a facilitating impact on the processing of dichotically presented verbal stimuli. Dichotic listening is used to measure cerebral dominance; however, it has also been implicated in attentional processing (Ojemann, 1985; Bhatnagar *et al.*, 1989). Left thalamic stimulation has also been noted to facilitate calculation accuracy when subjects count backward by threes from a given double-digit number (Ojemann, 1983).

Centromedianum Nucleus Multiple sources of data obtained from the stimulation of the left centromedianum, a previously unexplored intralaminar thalamic nucleus, suggest the importance of the mesothalamic reticular formation in the processing of language. Many reports of stimulation in the left CM have shown that its stimulation results in a facilitatory influence on the processing of language functions, which were measured in terms of the correctness of responses, number of errors, patients' response latency, sentence comprehension, and nonverbal reasoning (Bhatnagar and Mandybur, 2005). In addition to a facilitatory effect on the processing of language, CM stimulation was also found to have facilitated calculation rate and accuracy if the patient was asked to count backward by threes from double- or triple-digit numbers (Bhatnagar and Mandybur, 2005). A positive effect of the CM stimulation was also noted on the auditory transmission of dichotically presented verbal stimuli even from the nondominant left ear, which only indirectly projects to the left dominant cortex (Bhatnagar *et al.*, 1990).

Furthermore, therapeutic mesothalamic stimulation used to relieve pain has also had an ameliorating effect on stuttering behavior (Andy and Bhatnagar, 1992). Elimination of stuttering-like behavior was attributed to an increased motor speech synchronization that was rendered by the stimulation of the left CM nucleus. These speech-fluency-related ameliorating effects lasted at least 2 to 3 years with chronic stimulation since the patients were last assessed. Microelectrode recording performed by Bechtereva *et al.* (1992) demonstrated that systems of thalamic neurons in the CM and VL thalamus respond selectively to word recognition. Further studying neuronal activity of subcortical (mainly striatal–pallidal and thalamic) neurons in lexical processing, Gogolitsin and Nechaev (1990) noted that the thalamic neurons fired in specific patterns in response to certain semantic categories.

Role of Basal Ganglia in Language Functions

In the clinical and scientific literature, most attention has been paid to the motor function of the basal ganglia nuclei. Consisting of a series of long and short loops and subloops, the basal ganglia nuclei have been known to process and refine the cortically generated input before channeling it back to the cortex through its output circuitry involving the internal globus pallidus, substantia nigra pars reticulata, and lateral thalamic nuclei. A few investigations, which focused on the behavioral dysfunctions in patients with basal ganglia lesions, have indicated that some of its neuronal circuitry is also involved in nonmotor functions (Brunner *et al.*, 1982). Investigations focusing on the retrograde transneural transport of the McIntyre-B strain of HSV1 have revealed that in addition to its output to motor and oculomotor areas, a substantial amount of basal ganglia output is to nonmotor areas that include the lateral prefrontal cortex (Brodmann areas 9, 12, and 46) and the inferiotemporal region (Middleton and Strick, 2000) (see Figure 4). The prefrontal cortex, as part of the executive brain, is involved in planning, learning, attention, problem solving, and other essential cognitive functions, and the ventrotemporal cortex is involved in memory. With efferents to and afferents from these regions, basal ganglia nuclei are anatomically situated to render a broader influence on cortically mediated functions.

Recognition for the potential contributions of the basal ganglia to higher mental function has emerged in the past 10–15 years. The clinically confirmed presence of the cognitive disorders, seen in virtually all patients with Huntington's chorea and in some patients with Parkinson's disease, has provided strong support for the cognitively relevant neural circuitry in the striatum and the reciprocally connected pars reticulata region of the substantia nigra (Middleton and Strick, 2000).

Posterior Ventral Pallidum

The appreciation of a cognitive role for the basal ganglia is coupled with the resurgence of interest in

	Cognitive			Sensory		Motor			Oculomotor

surgical intervention for the remediation of motor disorders. The pallidal region of the basal ganglia became the primary target for the surgical treatment of medically intractable Parkinson's disease shortly after it was reconsidered on clinical and anatomical grounds by Laitinen *et al.* (1992). Only a few studies, though, actually categorized the influence of the globus pallidus on language function. Recording from single neuronal units has shown that only 19% of the recorded neurons in the globus pallidus interna were related to movement (Sterio *et al.*, 1993). Though it may actually have many heretofore uncharted functions, it does open the possibilities of many pallidal neurons participating in nonmotor functions such as language and cognition. Furthermore, chronic stimulation of the internal globus pallidus has resulted in a decline in verbal fluency and visuoconstructional skills, although no significant changes have been seen in overall levels of cognitive function (Troster *et al.*, 1997).

Subthalamic Nucleus

Within the complex neurocircuitry of the basal ganglia, the STN has been described as having a relatively central controlling relationship of basal ganglia output. With its strategic location adjacent to the inner basal ganglia loops, it is considered to be the preferred site for surgical interventions for medically intractable Parkinson's disease (Parent and Hazrati, 1995). A study involving bilateral subthalamic nucleus stimulator implantation showed prolonged postoperative semantic processing reaction times for a range of word types coded for meanings and meaning relatedness. Furthermore, the patients with the STN deep brain stimulators showed a significant improvement in postoperative lexical scores on the word test (revised) (TWT-R: a test of expressive vocabulary and semantics) but a decline in the accuracy of lexical decisions about words with multiple meanings (Whelan *et al.*, 2003). Additional studies involving the stimulation of the subthalamic nucleus have demonstrated a significant reduction in intraphrasal hesitation pauses, phonemic paraphasias, and morphosyntactic errors. Moreover, a clinically significant improvement was noted in lexical retrieval. There appears to be an implicit linguistic phenomenon, occurring mainly within the basal ganglia circuitry, which is benefited by stimulation-induced recovery of function within the basal nuclei and the overall relationship between the basal ganglia circuitry and the cerebral cortex (Zanini *et al.*, 2003).

Discussion

The full scope of the true nature of the brain's functional mechanism remains a mystery. Current knowledge of the brain and its function exists rather in bits and pieces, largely because the techniques (focal stimulation, positron–emission tomography, functional magnetic resonance imaging, and lesion evidence) have their inherent limitations and usually focus on a single functional property in any one study.

Considering the immense complexity of language, little is known about the precise ways in which the cortical and subcortical structures interact and participate to influence language acquisition and its ultimate formulation. Focal stimulation, which comes closest to focusing on the brain *in vivo*, is geared more for safety and side effect profiles with regard to neurosurgical interventions on these nuclear structures. In addition, confounding problems may accrue due to bilateral surgical intervention, in which the role of the dominant hemisphere cannot be independently measured. Comparisons of 'older' studies and more modern ones may also prove challenging because of changes in nuclear nomenclature as well as technological advances in surgery and imaging. With these issues in view and the limitations of techniques in mind, one can secure at least some partial understanding of the roles that cortical and subcortical structures play and of their interaction in the acquisition, regulation, and generation of speech, memory, and language functions.

Elicitation Techniques for Spoken Discourse

P Como, Università di Napoli 'Federico II,' Napoli, Italy

People who work with spoken discourse almost always have to face the problem of data collection. This is one of the most crucial phases of every research project insofar as the final results will be strongly dependent on the nature and the quality of the data gathered. For this reason, it is very important to choose the most appropriate technique, or a combination of techniques, in accordance with the specific purposes and the theoretical goals of the research. However, most important, it is essential to be aware of the intrinsic limits of each elicitation strategy.

The techniques used to elicit spoken discourse can be classified as methods based on observation and methods based on interview, depending on the approach of the researcher to the reality being investigated. During observation, the researcher observes and may participate in community life, trying to minimize the effects of his or her presence. On the other hand, interview methods influence the investigated community to a greater degree, creating a more unnatural situation, and consequently elicit less natural discourses.

Observation

Observation methods do not necessarily require the presence of the researcher in the community under investigation. Observation without participation implies that the interviewer remains outside the group and records it with candid instruments. An adequate unobtrusive data collection procedure is useful, for instance, in laboratory classrooms or in particularly delicate situations, but in general participant observation is preferred. In this case, the researcher participates in community life as an insider so that the individuals interact with him or her just as they would with anyone else. The prolonged presence in the field will provide the researcher with the chance to observe and collect (transcribing, recording, and videotaping) a large amount of linguistic and social data in almost natural settings and contexts.

Observation techniques developed by cultural anthropologists (Stocking, 1983) have been used in many different research fields: in ethnography of speaking by Blom and Gumperz (1972), in sociolinguistics (e.g., Labov (1972a) studied adolescent peer groups in south central Harlem using long-term participant observation), and in conversational studies (see, for example, Tannen (1981), who described the New York Jewish conversational style on a corpus of

Elicitation Techniques for Spoken Discourse

P Como, Università di Napoli 'Federico II,' Napoli, Italy

© 2006 Elsevier Ltd. All rights reserved.

People who work with spoken discourse almost always have to face the problem of data collection. This is one of the most crucial phases of every research project insofar as the final results will be strongly dependent on the nature and the quality of the data gathered. For this reason, it is very important to choose the most appropriate technique, or a combination of techniques, in accordance with the specific purposes and the theoretical goals of the research. However, most important, it is essential to be aware of the intrinsic limits of each elicitation strategy.

The techniques used to elicit spoken discourse can be classified as methods based on observation and methods based on interview, depending on the approach of the researcher to the reality being investigated. During observation, the researcher observes and may participate in community life, trying to minimize the effects of his or her presence. On the other hand, interview methods influence the investigated community to a greater degree, creating a more unnatural situation, and consequently elicit less natural discourses.

Observation

Observation methods do not necessarily require the presence of the researcher in the community under investigation. Observation without participation implies that the interviewer remains outside the group and records it with candid instruments. An adequate unobtrusive data collection procedure is useful, for instance, in laboratory classrooms or in particularly delicate situations, but in general participant observation is preferred. In this case, the researcher participates in community life as an insider so that the individuals interact with him or her just as they would with anyone else. The prolonged presence in the field will provide the researcher with the chance to observe and collect (transcribing, recording, and videotaping) a large amount of linguistic and social data in almost natural settings and contexts.

Observation techniques developed by cultural anthropologists (Stocking, 1983) have been used in many different research fields: in ethnography of speaking by Blom and Gumperz (1972), in sociolinguistics (e.g., Labov (1972a) studied adolescent peer groups in south central Harlem using long-term participant observation), and in conversational studies (see, for example, Tannen (1981), who described the New York Jewish conversational style on a corpus of

spoken language collected during everyday and ordinary conversation).

These techniques are very demanding in terms of tact, energy, time, empathy, and emotional involvement, but they create an intimate space in which the participants can share personal stories in a more natural discourse. The negative aspect of this approach is that a great amount of work may be wasted. In fact, the actual data analyzed from the recordings are minimal compared to the total amount of speech and number of speakers recorded. Sometimes, data are not suitable for analysis due to the low quality of the recordings. Furthermore, natural data have specific weak points which render them difficult to analyze. The effects of variables such as power, distance, status, gender and age gap between interlocutors become difficult to identify and take into account. These factors are crucial in pragmatic studies and therefore may interfere with the research results. Nevertheless, methods based on observations are a very valuable means of exploring the nature of communicative norms and cultural values of the groups studied, and this awareness is also a basic prerequisite when using interviews.

Interview

The interview involves at least two participants with clearly defined roles: the interviewer, who selects the topics and asks questions, and the respondent, who should answer the questions. The interaction between the two is a complex and multifaceted speech event, highly reflective of the relationship and the power relation established between the involved parties (Briggs, 1986: 18). These asymmetrical participant roles have major implications for discourse structure (for a critical discussion of the problem, see Milroy, 1987: 39–67). It is important to be conscious of the effects of some independent variables: Sex, age, race, personality, and the interactional style of the interviewer and of the interviewee can 'bias' the course of the interview (for the influence of race, see Edwards, 1986). The variety of the language used by the interviewer, as well as his or her way of dressing and general behavior, can potentially condition the interviewee and the language choices made during interaction.

There are many different interviewing strategies. Depending on the organization of questions and the formality of the interaction, interviews can be structured or spontaneous. In structured interviews, the informant can be asked to merely respond to some questions or to perform more elaborate tasks, such as retelling a short story or commenting on some pictures. In spontaneous interviews, the informant is encouraged to speak as naturally as possible. The length of the interviews can vary: There are anonymous and rapid surveys or long interviews. The interaction can be face-to-face or mediated, for instance, on the telephone. Interviews can be carried out outside or in private houses or laboratories. Depending on the number of participants, one-to-one or group interviews can be conducted.

In the following sections, some of these features are briefly described.

Structured Interview

Face-to-face interviews can be structured in various ways: The sequence and formulation of questions and responses may be more or less predetermined. In traditional dialectology, for instance, fixed questionnaires were used to obtain words or group of words (phrase or sentences) of the local dialects. The informant was asked to translate items or longer sequences of the standard language, often being influenced by the way in which the interviewer formulated the question. On the contrary, to elicit spoken discourse it is preferable to use more flexible questionnaires with a set of questions organized around specific topics. The sequence and formulation of questions may vary in each interaction. Standardization does not seem to be a requirement, even in survey interviews (Houtkoop-Steenstra, 2000: 180).

Specific Techniques Sometimes it is necessary to integrate interviews with specific techniques designed to elicit relevant data. Determined syntactic or morphological variables or discourse units, for instance, can occur only sporadically or by chance during verbal interactions.

In order to obtain a more structured and complex discourse, the informant can be asked to perform a role. This technique has been used to investigate second language acquisition by adult immigrants (Perdue, 1993). A typical example is the 'shrunken sweater' role play where the informant played the role of a customer who wanted to return a shrunken sweater to a shop. The customer wanted to obtain a refund because the sweater had shrunk even though it had been washed according to the label. The researcher performed the role of the shop assistant who dealt with customer complaints. The speech produced by the informant in this simulation offered valuable data for studying argumentative sequences as well as many other linguistic functions.

Another technique consists of showing people a film and asking them to talk about what happened

in it (see Chafe, 1980). This strategy allows the elicitation of spoken narrative style when people talk about things they have experienced. It has been employed to study a series of varied topics in different languages, such as the cultural differences in oral narrative strategies (Tannen, 1980) and the factors influencing lexical choice (Downing, 1980).

Other methods used to elicit spoken discourse employ a set of pictures showing different images. The informant has to comment on the images or use them as a guide to invent a story. Moreover, to study the phenomena of the syntactic level, it can be useful to ask the informant to retell a relatively complex story heard on audiotape or narrated by the interviewer.

Spontaneous Interview

The previously described techniques allow the elicitation of discourse in a restricted context. On the contrary, the aim of the so-called 'spontaneous interview' is to create a relaxed atmosphere in which the informant can talk 'spontaneously' and produce so-called 'casual speech' (Labov, 1972b).

Spontaneous interviews in relatively casual contexts are crucial for the analysis of sociolinguistic cues. Unfortunately, the very fact that a person is being interviewed is the main obstacle in obtaining casual speech – that is, the style in which a minimum amount of attention is given to the monitoring of language. This is the famous observer paradox (Labov, 1972c: 121). One of the techniques suggested by Labov to overcome this problem was to change the conversation to a topic that the interviewees felt very strongly about, such as the 'danger of death.' This had the effect of causing the speakers to focus on what they were saying rather than on how they were speaking. However, field experience has shown that questions concerning the danger of death are not always effective in obtaining a more natural speech (Milroy 1987: 40–1). It is much more important for the interviewer to understand what topics are of principal interest to the speaker and seek to steer the conversation in those directions all the while showing interest and empathy.

The distinction of categorical speech styles strictly associated with the formality of the context (Irvine, 1979) has been questioned (Eckert and Rickford, 2001). As Wolfson (1976) argued, Labov's categories of speech styles presuppose that there exists a precise entity of natural, casual speech. That entity does not exist *per se*, but the speech is natural when appropriate for a situation and a goal. The speech elicited during an interview is strictly dependent on the interview, and the problem of spontaneity should not be overemphasized because most important is the analytical study of all the factors that play a role during the interview.

In spontaneous interviews, it is useful to employ a variety of topics to initiate the conversation, according to the characteristics of the informants (age, sex, social status, interests, and country). Indeed, the informants may be surprised that a stranger, armed with a tape recorder, is so willing to engage in conversation even though there is nothing in particular to talk about (Wolfson, 1976). The interviewer can encourage the emotional involvement and the naturalness of interaction by speaking of his or her own personal experience. He/her can also take turns in conversation so as to make the interaction more natural, but should avoid frequent overlapping or interruption of the interviewee.

The spontaneous interview therefore demands strong social skills and communicative and empathic capabilities: "Flexibility in this regard is the earmark of the successful interviewer" (Labov, 1972b: 103). An overarching requirement for a good interviewer is an honest and frank interest in the subject matter of his or her research and for the people helping him or her collect material for the study (Wolfram and Fasold, 1974).

Rapid and Anonymous Surveys

Instead of complex and long interviews (regarding interview length, see Milroy, 1987: 39), it can sometimes be useful to use rapid surveys to elicit comparable sets of phrases in a natural context and with significant time savings. One famous research project conducted using this method is described by Labov (1972c) and is usually referred to as the 'fourth floor study.' In this study, data were collected from the shop assistants of three New York City department stores. The interviewer asked them for the location of an item he or she knew was located on the fourth floor. The response of the store assistant obviously contained common items, at least 'fourth floor'; in fact the linguistic feature investigated was the /r/ in preconsonantal and final position.

The same principle of rapid survey can be applied using other formulations, such as asking for directions (Dittmar and Schlobinski, 1988). These techniques require a well-planned study with a topic properly defined before interviewing. On the other hand, they fail to collect social characteristics from the informants and the linguistic data have a very narrow field of analysis (Milroy, 1987). In addition, the quality of the recording can sometimes be poor.

Rapid interviews have also been conducted using the telephone, which is an easy way to obtain a short interaction complete with all the rituals of

salutations. For instance, Schegloff (1968) studied the ritualized sequence of opening moves in telephone conversations.

It is also possible to analyze natural registered telephone calls. Scollon (1998) analyzed the social practices in the interactive construction of business telephone calls, and Zimmerman (1992) studied the interactional organization of the talk occurring in calls to the 911 emergency telephone number. The disadvantage of this type of interview is the lack of paralinguistic features such as gestures and eye gazing. Although telephone speech is acoustically limited, it can furnish good data for discourse analysis.

Group Interview

As opposed to the individual interview, occasionally the group interview turns out to be useful. Group interaction overcomes the restriction produced by the formal context of the one-to-one interview. It is also possible to interview one person in the presence of friends. This can make the context more realistic and familiar. Sometimes the people attending may exert enough pressure on the interviewee that he or she does not shift his or her way of speaking. Sometimes, however, the opposite happens and the people present, who question the way the informant should talk, oppress him or her. In group interviews, each speaker should be recorded on a single track in order to avoid the overlapping of voices.

Recording

As Vaux and Cooper (1999) suggested, it is important to record as much of a field session as possible. Videotaping and recording can help to make an analysis more fine-grained, giving the researcher the chance to hear or to see a tape repeatedly in order to notice things that happen rapidly or only once.

Sometimes being recorded can make people feel self-conscious or embarrassed, talk unnaturally, or, in extreme cases, stop talking altogether. Nevertheless, experience demonstrates that very often people ignore the microphone, either because of their familiarity with recording equipment or because they get used to the machine or even forget it is there. This is particularly true for elderly informants.

To facilitate this process during the interview, it is necessary to direct as little attention as possible to the recording process. For example it can be useful to place the recorder on a chair, easily accessed by the interviewer but hidden from the speaker. It is preferable to use an unobtrusive digital audio tape along with a good microphone.

Occasionally, it may be interesting to tape surreptitiously people who do not know they are being studied. This questionable practice gives rise to legal as well as ethical issues, and in any case it is necessary to ask for permission afterward. Speakers generally do not like to be recorded without their knowledge.

Ethics

Finally, the gathering of spoken data gives rise to ethical issues. It is fundamental to respect the interviewee's rights. For instance, occasionally it is necessary to interrupt the recording or even cancel part of it due to the explicit request of the informant. This happens when people realize they have given too much information about their personal and private affairs.

The researcher must observe participants' legal rights and should obtain informed written consent from them for their participation in the project and also for the use of the data they provide (for an overview, see Johnstone, 2000: 39–57). In addition, in order to preserve anonymity, it is good practice to use pseudonyms for personal and street names.

How much information concerning the research should be imparted to the interviewee presents another ethical dilemma.

It is important that a researcher face these issues conscientiously and choose the best way to deal with them before starting work in the field.

Ellipsis

S Winkler, Tübingen, Germany

© 2006 Elsevier Ltd. All rights reserved.

The term 'ellipsis' is derived from the Greek *élleipsis*, and in modern grammatical theory most generally refers to the omission of linguistic material, structure, and sound. In various theoretical frameworks, the phenomenon of ellipsis has been conceived of as a special case of anaphora because the silent string in an elliptical sentence is dependent for its interpretation on being associated with something else in the context, as is the case with anaphoric expressions (see Schwabe and Winkler, 2003 for an overview).

Some examples of different types of ellipses are given in (1). In each of the elliptical constructions in (1a) to (1f), linguistic material is omitted, deleted, or simply left unpronounced. Nevertheless, the silent string in the elliptical clause, here marked by an underscore, can be recovered from the italicized string in the previous conjunct.

(1a) Manny *plays* the piano and Anna _ the flute. (Gapping)
(1b) They *play the piano* but Anna doesn't _. (VP-Ellipsis)
(1c) They *play* the piano better than Anna does _ the flute. (Pseudogapping)
(1d) Manny *plays the piano* and Anna _, too. (Stripping)
(1e) Someone's *playing the piano* but I don't know who _. (Sluicing)
(1f) Manny played a solo with one *hand* and Anna with two _. (NP-Ellipsis)

In (1a), the second conjunct is interpreted as *and Anna plays the flute*. The verb *plays* is gapped, and therefore the elliptical construction is called 'gapping.' In (1b), the complete verb phrase after the auxiliary is absent, forming a case of 'VP-ellipsis' (VPE). Whereas (1c) is parallel to gapping, because the verb *play* is missing, it also bears some features of VPE because the missing sting occurs after an auxiliary and therefore it is called 'pseudogapping.' The phenomenon in (1d), where everything is elided except *Anna* and the focus particle *too*, is called 'stripping.' In (1e), the complete sentential complement to the interrogative wh-phrase *who* is missing and is recovered from the antecedent conjunct. The final example in (1f) combines 'NP-ellipsis' (NPE) after the numeral *two* with gapping of the string *played a solo*.

The constructions in (1) bear a set of similar features: they occur in coordinate structures; the second conjunct contains a gap or a silent site, and therefore Ø is referred to as the 'elliptical clause or phrase'; at the same time, the second conjunct contains a means

In (1b), the complete verb phrase after the auxiliary is absent, forming a case of 'VP-ellipsis' (VPE). Whereas (1c) is parallel to gapping, because the verb *play* is missing, it also bears some features of VPE because the missing sting occurs after an auxiliary and therefore it is called 'pseudogapping.' The phenomenon in (1d), where everything is elided except *Anna* and the focus particle *too*, is called 'stripping.' In (1e), the complete sentential complement to the interrogative wh-phrase *who* is missing and is recovered from the antecedent conjunct. The final example in (1f) combines 'NP-ellipsis' (NPE) after the numeral *two* with gapping of the string *played a solo*.

The constructions in (1) bear a set of similar features: they occur in coordinate structures; the second conjunct contains a gap or a silent site, and therefore Ø is referred to as the 'elliptical clause or phrase'; at the same time, the second conjunct contains a means

of picking up the missing material from the first conjunct, often referred to as the 'antecedent clause;' the missing material or 'antecedent property' is interpreted in the elliptic site at the level of semantic interpretation; finally, the second conjunct contains elements that remain – so-called 'remnants.' The burning issue raised by the elliptical constructions in (1) for any theory of language is this: how is it possible that we understand more than we actually hear? The answer to this question lies in the most economic division of labor between the interfaces connecting form (syntactic structure), sound (PF)/(LF), and meaning as represented in the model of grammar (Chomsky, 1995).

Within the current theory of grammar, two prevailing research paradigms can be isolated: the deletion accounts and the nondeletion accounts (see Johnson, 2001 for details). Each of these approaches makes different predictions with respect to the three core questions relating to ellipsis: (i) how is ellipsis represented? (ii) how is ellipsis interpreted? (iii) how do information structure and focus contribute to the licensing and interpretation of ellipsis? These questions address the syntax, the semantics, and the information structure of ellipsis.

Syntax

By far the most widely studied types of ellipses are gapping and VPE, as given in (1a, 1b). The most basic observations about these two types of ellipses that any syntactic analysis must account for are the following: (i) VPEs target a phrase, whereas a gap need not be a phrase; (ii) VPEs can precede their antecedents, but a gap cannot; (iii) VPEs can occur in a subordinate clause, but a gap cannot; (iv) VPE is not subject to Ross's Complex NP-Constraint, but a gap is; (v) VPE can refer to an antecedent outside the clause, but a gap must find its antecedent within the first conjunct. These core differences are illustrated in (2) to (6), where the a-examples contain VPEs and the b-examples contain gaps.

(2a) Mr. Katzenstein certainly would have *learned something*, and it's even possible that Mr. Morita would have _ too. (Penn Treebank)
(2b) As a result consumer prices for the first 10 months of 1989 *surged* by 5% and wholesale prices _ by 1.3%. (Penn Treebank)

(3a) Although we think he shouldn't _ , Bush might *win the election*.
(3b) *Although we _ Bush shouldn't win the election, they *think* differently.

(4a) But like Mr. Egnuss few expect program trading to be *halted entirely* and a surprising number doubt that it should be _. (Penn Treebank).
(4b) . . .the Colombian minister of economic development said Brazil *would give up* 500 000 bags of its quota and (*then he announced that) Colombia _ 200 000 bags. (Penn Treebank)

(5a) John didn't *hit a home run*, but I know a woman who did_. (Sag, 1977)
(5b) *John didn't *hit* a home run, but I know a woman who _ a smash.

(6a) The thought came back, the one nagging at him these past four days. He tried to *stifle it*. But the words were forming. He knew he couldn't_. (Hardt, 1993);
(6b) [same context] *He knew he couldn't _ them.

VPE and gapping differ with respect to one further characteristic, usually referred to as the 'parallelism requirement.' Under this requirement, gapping must occur in coordinate structures and requires its remnants to occur in a contrastive relationship to their antecedents, as in (7). VPEs do not require parallel structures. The remnants are typically free to assume various discourse functions depending on the context, as in (8). Focused and accented elements are capitalized.

(7a) MANNY *plays* the PIANO and ANNA _ the FLUTE.
(7b) *MANNY *plays* the PIANO and ANNA _ the piano.
(7c) *MANNY *plays* the PIANO and Manny/he _ the FLUTE.

(8a) Manny *plays the piano* but ANNA DOESN'T _.
(8b) Manny *plays the piano* but he claims he DOESN'T _.

In current generative theory, the most influential account of ellipsis is the phonological deletion account assumed in Chomsky (1995) among many others. Historically, it is closely related to the syntactic deletion account, also called the 'strict transformational position,' as proposed by Ross (1967), which assumes that "all anaphoric processes are transformations that involve deletion" (Hankamer and Sag, 1976: 394). The basic idea of the PF-deletion account is that the computational system of human language hands on the fully derived sentence to the interfaces, PF and LF. At LF, the incoming sentence is interpreted. At PF, ellipsis is achieved by deletion of redundant material. PF-deletion accounts are based on the assumption that elided material has abstract features of phonetic and phonological representation, but that grammar contains a means of blocking its pronunciation. A

straightforward PF-deletion hypothesis is given in (9), as for example assumed by Kuno, 1976; Rooth, 1992; Merchant, 2001:

(9) Phonological Reduction Hypothesis:
Given material is deaccented or deleted at Phonological Form.

The term 'given material' in its original definition by Halliday (1967) refers to "recoverable information" in general. The hypothesis that explains the focus pattern of the remnants is given in (10), as for example assumed by Kuno, 1976; Rooth, 1992; Merchant, 2001:

(10) Contrastive Focus Hypothesis:
Given or redundant information licenses contrastive focus on the remnants.

The term 'contrastive focus' is informally defined as evoking a suitable set of alternatives from which a subset is chosen. The PF-deletion account predicts that an elliptical site is fully structurally represented, but not phonologically realized, as symbolized by the strike-through in (11).

(11) They *play the piano* but ANNA DOESN'T ~~play the piano~~.

The hypothesis (9) applied to the examples in (1a–f) correctly accounts for the elliptical sites, because in each case there is an antecedent in the coordinate conjunct that constitutes given material and thus can be elided in the second conjunct. Hypothesis (10) accounts for the ungrammaticality of (7b, c). Note, however, that neither of these hypotheses can adequately explain the difference in syntactic distribution of VPE and gapping illustrated in (2)–(6). Consider the alternative, or nondeletion account.

The nondeletion or proform accounts (a modern variant of the 'strict interpretive position') reject the claim that unpronounced material has syntactic representation. Instead they claim that "all anaphors (pronominal or null) are present in the underlying representation, and that no anaphors are derived transformationally" (Hankamer and Sag, 1976: 394). They propose that general mechanisms governing the recovery of meanings from context can be put to work to analyze elliptical constructions. One influential proposal was put forward by Lobeck (1995), building on much earlier work, in particular, Williams (1977) and Chao (1988). The main aim was to account for the distribution of ellipses by combining two assumptions: (i) ellipses are empty (non-nominal) proforms and are constrained in the same way as the empty nominal proform *pro*; (ii) ellipses must be analyzed as complements of a functional head. The result of applying (i) and (ii) to the elliptical constructions in (1) is that they account for VPE (1b), sluicing (1e) and NPE in (1f), but not to (1a, 1c, 1d). In VPE, sluicing and NPE, the complement of a functional head is empty (e), as illustrated in (12):

(12a) They *play the piano* but [$_{TP}$ Anna [$_{T'}$ doesn't [$_{VP}$ e]]].
(12b) Someone's *playing the piano* but I don't know [$_{CP}$ who [$_{C'}$ +wh [$_{TP}$ e]]].
(12c) Manny played a solo with one *hand* and Anna with [$_{DP}$ two [$_{N}$ e]].

This characterization fits in nicely with the claim that the set of elliptical constructions in (1) form two distinct natural classes, discourse-bound, as in (12) and sentence-bound as in (13), a distinction inspired by Williams' (1977) original differentiation between sentence grammar and discourse grammar (1977: 102) and further developed in Winkler (to appear). The examples in (13) comprise the sentence-bound ellipses, gapping and stripping, which are characterized by the absence of the phrasal head and other material in the elliptical clause.

(13a) Manny *plays* the piano and Anna [$_{VP}$ [$_{V}$ ~~plays~~] the flute].
(13b) Manny *plays the piano* and [$_{TP}$ Anna [$_{T'}$ ~~plays the piano~~]], too.

The distinction between sentence-bound and discourse-bound ellipses also provides an explanation for the data in (2) to (6). VPE is a discourse-bound ellipsis and can be accounted for by a proform analysis; gapping is a sentence-bound ellipsis and is more syntactically constrained, in a sense to be made more precise in the section on information structure.

Semantics

The question of how ellipsis is interpreted is closely connected to the nature of the identity that holds between the ellipsis and its antecedent. The PF-deletion account has the advantage that the syntactic structure in the elliptic site is strictly identical to its antecedent and is preserved for semantic interpretation at LF. However, it has the disadvantage that additional mechanisms must be assumed for cases where the strict syntactic identity between the ellipsis and its antecedent is not obeyed, as in (14):

(14) Speaker A: Do you think they will like me?
Speaker B: Yes, I'm sure they will _.

Example (14) is a case of VPE. It constitutes a problem for any theory that requires the ellipsis site and the antecedent site to be syntactically identical, because it can only be understood as *I'm sure they will* ***like you***. Instead of maintaining the referent of the antecedent VP (strict identity), the pronoun within the antecedent VP changed its referent in the

elliptic site, a phenomenon often referred to as 'sloppy identity.' However, the phenomenon of sloppy identity does not pose a problem for proform accounts that treat VPE on a par with other proforms, where the sloppy identity reading, as observed in (14), results from the fact that information retrieval operations are freely ordered.

There are three further syntactic effects on variables that are not respected under ellipsis and thus challenge the deletion account. First, it has been observed by Reinhart (1983) that for bound variables, like reflexives, the strict reading is systematically absent under VPE, as in (15a). Note, however, that the reflexive can acquire a strict interpretation when the coordinating conjunction *and* is replaced by the causal conjunction *because*, as in (15b) (from Hardt, 1993). Even context can trigger the strict reading, as in G. W. Bush's statement directed to Sadam Hussein (October 2002), given in (15c). The intended reading occurs in square brackets.

(15a) John voted for himself and his lawyer did _ too. [voted for himself]
(15b) John$_i$ defended himself$_i$, because his lawyer didn't_ [defend him]
(15c) "You disarm, or we will_[disarm you]." (G. W. Bush)

A second case in which syntactic constraints are not respected under ellipsis is illustrated in (16). Under the PF-deletion approach, (16) would be predicted to be ungrammatical due to the violation of Condition C of the Binding Theory. However, the Condition C effect is absent under VPE.

(16) I expected Jan$_i$ to win even when he$_i$ didn't_. [~~expect himself$_i$ to win~~].

A third case in point is the behavior of the polarity expression in (17). Under a PF-deletion account, (17) would be expected to be ungrammatical.

(17) Although Philip Morris typically tries to defend the rights of smokers with free-choice arguments, this has nothing to do with cigarettes, nor will it ever_. [have anything to do with it.] (Penn Treebank)

Note that a syntactically identical copy of the antecedent in the ellipsis site would result in ungrammaticality.

A further problem for the strict syntactic identity account stems from the observation that VPE can have split antecedents. As expected under the proform account, VPE patterns with regular pronouns with respect to split antecedents. A pronominal split antecedent example is given in (18a) and a case of VPE with a split antecedent is given in (18b):

(18a) Ben$_i$ told Jan$_j$ that they$_{i,j}$ will win the game.
(18b) Susan wanted to write a letter and John wanted to call her, but neither of them did. (Napoli, 1985)

The relevant observation with respect to example (18b) is that there are two possible antecedents for each of the VPEs. The interpretation of (18b) cannot be achieved by a deletion account that preserves syntactic identity. The required meaning cannot be derived from coordinating the respective verb phrases, because *write a letter and call her* does not provide the right meaning. We expect something like *but neither did Susan write a letter nor did John call her.* It seems that any account that is based on mere deletion of syntactically identical material will have problems accounting for these data.

The final point that challenges accounts that assume syntactic identity between the elliptic site and its antecedent is examples that show that VPE does not require parallel syntactic form between antecedent clause and elliptical site, as illustrated in (19a, b):

(19a) A lot of this material can be presented in a fairly informal and accessible fashion, and often I do_. (N. Chomsky, cited in Dalrymple *et al.*, 1991).
(19b) I haven't had a chance to talk, but I'm confident we'll get a bill that I can live with if we don't_. (G. W. Bush, Brussels, 2001).

Example (19a) shows that VPE in its active form can occur with a passivized antecedent verb phrase, and (19b) demonstrates that VPE can even find its antecedent in an embedded antecedent clause.

Information Structure

In recent publications on ellipsis and information structure, the PF-deletion account and the proform account make different predictions about how intonation and focus contribute to the licensing and interpretation of ellipsis. The claim is that the information-structural function of sentence-bound and discourse-bound ellipses differs and is signaled by different intonational features. Concentrate on two naturally occurring examples, one from each group: gapping, a sentence-bound ellipsis, is given in (20), and VPE, a discourse-bound ellipsis, in (21).

(20) It's probably true . . . that the system is so hierarchical
[that only the ASSISTANT manager can talk to the MANAGER
and the MANAGER to the GENERAL manager . . .] (Penn Treebank)

(21) Why does Betty think I was trying to kill myself? [On the principle that one swallow doesn't make a summer, but TWO probably DO], dear girl. (Walters (1996) *The Dark Room*. London: Pan Books, p. 42.)

The following pattern emerges. The sentence-bound and the discourse-bound ellipses have different information-structural functions, as stated in (22a, 22b).

(22a) Sentence-Bound Ellipsis:
The information-structural function of sentence-bound ellipsis is the isolation of contrastive foci or topics.

(22b) Discourse-Bound Ellipsis:
The information-structural function of discourse-bound . . . is marking the elliptical material as anaphoric or 'given.'

(22a) applied to the gapping construction in (20) predicts that the accented phrases represent contrasts. The first remnant of the elliptical clause *manager* is a contrastive topic; the second remnant *general manager* is a contrastive focus. (22b) must be applied to (21) and predicts that the elided material – here the NP *swallows* and the VP *make a summer* – marks given material. The fact that the functional elements immediately preceding the ellipsis sites are accented is due to a general rule of focus that regulates that the head of a phrase is accented if the argument cannot be (Selkirk, 1995).

Conclusion

Linguistic research over more than three decades has contributed significantly to our understanding of the different types of ellipses, the most prominent of which have been discussed here. The most comprehensive theories are those that recognize ellipsis as an interface phenomenon between syntax, semantics, and information structure. However, many aspects of how the different components work together still remain to be worked out.

This article is reproduced from the previous edition, volume 3, p. 1106, © 1994, Elsevier Ltd.

Ellis epitomized the life and career of the liberal-minded Victorian gentleman-scholar. Born into a comfortable middle-class family in Hoxton, London, on June 14, 1814, and supported financially for his entire life by a bequest, he was able to benefit from – and react to – the type of education provided by Shrewsbury, Eton, and Trinity College, Cambridge. His academic pursuits, mostly deriving from schoolboy interests and experiences, ranged over phonetics, music (especially singing), acoustics, mathematics (especially geometry), education, literature – and even horse taming.

He was drawn to phonetics by the mixed dialect areas in which he spent his early years: Hoxton, with its working-class Cockney speakers; Shrewsbury, with its mixture of Welsh and English accents; and Eton and Cambridge, with their aristocratic and upper middle-class speakers of RP. Contact with Isaac Pitman (*see* **Pitman, Isaac, Sir (1813–1897)**) led to joint developments in spelling reform (e.g., their 'Phonotypical Alphabet' of 1847) and shorthand. Publications on phonetics and spelling reform in the 1840s (1844, 1845, 1848) established Ellis as a major figure in these two fields. As a life-long advocate of the educational advantages of a reformed spelling of English, Ellis devised many systems, two of which, 'Palaeotype' and 'Glossic,' were to be utilized as phonetic notations (in the years before the development and near-universal acceptance of the IPA's alphabet).

The work for which Ellis deserves to be remembered is his *Early English pronunciation* (1869–1889), a five-volume description and discussion of the pronunciation of English from the Middle Ages to the late 19th century. Particular attention is paid to reconstructing the pronunciation of English during the Chaucerian and Shakespearian periods. For the 19th-century portion of the work, Ellis enlisted the help of hundreds of informants and a small group of phonetician–dialectologists. The result was the first major exposition of the dialect speech of the British Isles (together with some colonial and ex-colonial varieties); it was the precursor of the *Survey of English dialects* (*see* **Orton, Harold (1898–1975)**). His notations, although somewhat opaque to 21st-century users of IPA, reveal an astonishing array of detailed information about the allophony of 19th-century accents.

He graduated B.A. from Cambridge in 1837, was awarded the L.L.D. by Cambridge just months before his death, and was appointed F.R.S. in 1864. He died in West Kensington, London, on October 28, 1890.

Ellis, Francis Whyte (ca. 1778–1819)

R Chatterjee, Lado International College, Silver Spring, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

Among British civil servants of the colonial period in India who performed services to linguistics, few names are more prominent than that of Francis Whyte Ellis. He sailed to India as a young man of no more than eighteen years and joined the Madras Civil Service. In the early 1800s he held various positions, becoming Collector of Madras in 1811. He died in 1819 while at that position. Accounts differ as to the cause of death, from swallowing a poisonous substance to cholera. By that time, he had planned various publications that can no longer be traced. One account has it that after his early death his cook was able to stoke the kitchen fires for a long time with manuscripts Ellis had left behind.

As a pioneering European scholar Ellis occupies a place in Dravidian studies analogous to that of Sir William Jones in Indo-European. "As early as 1816," says Bhadriraju Krishnamurti in his *The Dravidian languages,* "Ellis . . . in his *Dissertation on the Telugu Language,* asserted that 'the high and low Tamil; the Telugu, grammatical and vulgar; Carnataca or Cannadi, ancient or modern; Malayalma or Malayalam; and Tuluva,' are the members 'constituting a family of languages which may appropriately be called the dialects of South India;' . . . his purpose was to show that Tamil, Telugu and Kannada 'form a distinct family of languages' with which 'the Sanscrit has in later times, especially, intermixed, but with which it has no radical connection.'" Krishnamurti goes on to note that Ellis "presented considerable material, mainly lexical and some grammatical, from Telugu, Kannada and Tamil in support of his hypothesis."

Ellis's scholarly interests were wide-ranging. He was a good scholar of Sanskrit. His work on proprietary right to land in South India was highly regarded. So was his metrical translation of and commentary on the most famous of classical Tamil literary works, Valluvar's *Kural*. He did pioneering work collecting South Indian inscriptions.

Ellis decided to commit his life only to research until the age of 40, and only then to begin publishing. Unfortunately his life was cut short during a manuscript-collecting expedition when he had barely reached that age. Nevertheless, he had published a study marking the birth of comparative Dravidian linguistics, the somewhat obscurely entitled 'Note to the Introduction' to Campbell's *Grammar of . . . Teloogoo* (1816). On this firm foundation later scholars, such as Caldwell, Burrow, Emeneau, Krishnamurti, and others, were able to build so successfully.

The Scotsman James Elphinston was a latecomer to the spelling reformers. He was born in Edinburgh in 1721 and spent the first 32 years of his life in Scotland. Then he went to England, where he opened a school at Brompton, which he later moved to Kensington. For him teaching the mother tongue that he loved intensely had absolute priority, followed by French, which he had acquired in Paris and spoke fluently, and then the classical languages. It is not known why he gave up his educational activities in 1776.

Elphinston wanted to teach the pronunciation used in the London area, and for this his language

Elphinston, James (1721–1809)

W Viereck, Universität Bamberg, Bamberg, Germany

© 2006 Elsevier Ltd. All rights reserved.

The Scotsman James Elphinston was a latecomer to the spelling reformers. He was born in Edinburgh in 1721 and spent the first 32 years of his life in Scotland. Then he went to England, where he opened a school at Brompton, which he later moved to Kensington. For him teaching the mother tongue that he loved intensely had absolute priority, followed by French, which he had acquired in Paris and spoke fluently, and then the classical languages. It is not known why he gave up his educational activities in 1776.

Elphinston wanted to teach the pronunciation used in the London area, and for this his language

textbooks of 1756 and 1765 are valuable sources. He spoke, for instance, monophthongal [e:] and [o:], whereas Received Pronunciation today uses [e] and [ə], and he articulated non-prevocalic /r/ regularly. Elphinston's interest was focused on form. Spelling was his main concern, and he viewed both grammar and word formation from this standpoint.

His major work, *Propriety ascertained in her picture,* in which he improved his spelling system, dates from 1786–1787. Volume 2 of this work is particularly valuable. As early as 1760, Elphinston had collected, corrected, and enlarged older lists of Scotticisms, and in Volume 2 he also dealt with the peculiarities of the pronunciation and sentence structure of his native dialect. With this book Elphinston acquired a unique position among British writers on dialect.

In the 1790s he published *Forty* (later *Fifty*) *years' correspondence,* transcribed into his script. The following is a specimen from a letter to Samuel Johnson's biographer James Boswell: "Inglish Orthoggraphy waz no more known to' dheir Author, dhan to' moast ov my oddher Correspondents." As can be seen from this sample, one of Elphinston's ideas was to double consonants to mark stressed short vowels. In 1790, 1795, and 1797 he published popular versions of his simplified spelling scheme. There was, however, little interest in the aesthetic aspect of English at the time, but rather a demand for prescriptive grammars that Elphinston's work did not meet. Consequently, his reform proposal failed. Coming from a grammarian, Elphinston's observations on the problems of number in English are especially noteworthy. For him, the English grammar was the basis of a universal grammar.

E-mail, Internet, Chatroom Talk: Pragmatics

D Stein, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany

© 2006 Elsevier Ltd. All rights reserved.

Scope and Purpose

The notion of the Internet comprises several elements: the ensemble of technical possibilities resulting from computers being linked to each other in computer networks; the types of communicative situations and types of language used in those situations; the body total of its users; and the sum of all Net communities using language. All of these elements define situations of language use. In addition, the Internet comprises all websites, which may be linked to all kinds of use situations. This article will deal exclusively with uses that situations such as chats, e-mail, and lists have in common. All of these genres essentially involve the use of language in an interactive, human-to-human way.

The following discussion will only deal with interactive Internet genres. Just as in written and spoken language, there are great differences between these genres; the following discussion will try to identify aspects of language that apply to all such genres, even if to varying degrees, in the same way that we can make useful generalizing statements about written and spoken language as basic medial varieties. The following discussion will include technical details of the Internet only to the extent that such details are needed to account for specific uses of language on the Internet. The discussion presupposes a basic knowledge of the Internet and its resources.

Emblems

F Nuessel, University of Louisville, Louisville, KY, USA

© 2006 Elsevier Ltd. All rights reserved.

The term 'emblem' has multiple meanings or references. In its most general usage, it may refer to such artifacts as coats of arms, flags, heraldry, university seals, and religious icons (the crucifix). These emblems indicate membership and ownership.

A second usage is the emblem book, the origin of which is attributed to the Italian lawyer Andreas Alciatus, whose book *Emblematum liber* (1521) contained a series of emblems. This genre subsequently became enormously popular as Daly (1979) attests. In its printed format, the emblem itself consists of three parts, all with Latin designations, in the following sequence: an *inscriptio* (motto), a *pictura* (visual image), and a *subscriptio* (short text).

Modern nonliterary exemplars of the emblem appear in official governmental artifacts. The U.S. penny, with its depiction of the bust of Abraham Lincoln on the obverse and the Lincoln Memorial on the reverse, is typical. The obverse also has the texts 'In God We Trust,' 'Liberty,' and the year in Arabic numerals, whereas the reverse has the Latin motto 'E pluribus unum' ('one from many'), and the texts 'United States of America,' and 'One Cent.' In this sense, this unit of coinage, as is the case with most world currency or postage stamps, is a prototypical specimen of the emblem with its conventional tripartite configuration. Many corporations and organizations produce emblems to symbolize their product or service to the public.

The origin of the word *emblem* as a semiotic term derives from Efron (1941), who first used this expression to refer to a communicative culture-bound gesture. Efron (1941) used this term differently from Ekman and Friesen (1969: 63) because he meant it to be encoded arbitrarily, and not iconically. The emblem is now a part of the nonverbal repertoire of linguistic signs. In their now classic essay on nonverbal behavior, Ekman and Friesen (1969) use the term *emblem* as the first in a five-part categorization (emblem, illustrator, affect display, regulator, adaptors) of nonverbal expressions. They define (Ekman and Friesen, 1969: 63) emblem as "those nonverbal acts which have a direct verbal translation, or dictionary definition, usually consisting of a word or two, or perhaps a phrase." In this sense, an emblem usually consists of a gesture that corresponds to a single word in a language (e.g., the 'V,' or 'victory' sign signified by holding the index finger and the middle finger in the form of the letter 'V,' with the fingers that are clenched facing away from the body).

Emeneau, Murray Barnson (b. 1904)

A Kaye, California State University, Fullerton, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Born on February 28, 1904, in Lunenberg, Nova Scotia, Murray Barnson Emeneau grew up there studying French, German (German, Standard), Latin, and Greek (see Emeneau, 1991). Combining a background in the classics, general linguistics, and anthropology, he became one of the greatest linguistic Indologists of all time. A prolific author, no linguist interested in India can afford not to read him, while every general linguist will profit from his lucid prose, no matter what the field of specialization. Among his most noteworthy contributions are his work on the Indian *Sprachbund*, bilingualism and structural borrowing, linguistic prehistory, as well as Dravidian comparative linguistics and etymology.

Emeneau received his B.A. in 1923 from Dalhousie University and another B.A. and an M.A. from Oxford University in 1926 and 1935, respectively, where he was a Governor-General's Gold Medalist in 1923 and a Rhodes Scholar from 1923 to 1926. Among his other notable achievements are Guggenheim Fellowships in 1949–1950 and 1956–1957, Faculty Research Lecturer at the University of California, Berkeley during 1955–1956 (the highest honor awarded a Berkeley faculty member), and Wilbur Lucius Cross Medalist from the Yale University Graduate School in 1969. He was founder and first chairman of the Department of Linguistics at UC Berkeley in 1953, where he served on the faculty from 1940 to 1971. He holds honorary degrees from the University of Chicago, 1968; Dalhousie University, 1970; University of Hyderabad, 1987; and Vidyavachaspati K.S.D. Sanskrit University, 1999. He served as Linguistic Society of America President in 1949; Editor of the Journal of the American Oriental Society from 1941 to 1951; and President of the American Oriental Society in 1954–1955.

Emeneau's overall approach to linguistics was influenced by the Boasian and Sapirian traditions, which consider it a major branch of cultural anthropology. Since academic positions were hard to secure during the years of the Great Depression, he went off to British India on a fellowship from Yale, the American Council of Learned Societies, and the American Philosophical Society. There he did fieldwork from 1935 to 1938 in the Nilgiris on three little-known Dravidian languages: Toda, Kota, and Kodagu, as well as in central India, where he studied Kolami. This pioneering research resulted in numerous publications (e.g., Emeneau, 1944–1946, 1955, 1971, 1984; Burrow and Emeneau, 1984).

Thoroughly versed in Greek, Latin, Sanskrit, and comparative Indo-European, Emeneau brought with him a superb background for his (1931) Ph.D. dissertation, an edition of a Sanskrit folk tale text. His rigorous training under Franklin Edgerton and Edgar H. Sturtevant, together with his experience in linguistic fieldwork (see, e.g., Emeneau, 1951), led to his innovative research of the Indian linguistic area. Although the notion of the *Sprachbund* was known from the Caucasus, the Balkans, and the northwest coast of the United States, Emeneau's investigation of the Indian scene describes a situation in which "languages belonging to more than one family show traits in common which do not belong to the other members of (at least) one of the families" (Emeneau, 1980: 127). The relationship among the Indo-Aryan, Dravidian, and Munda families is a direct reflection of the linguistic history and prehistory of India, a field which he cultivated.

The genetic relationship among the Dravidian languages was of interest to him from the very beginning. Emeneau correctly theorized that the relationship among Latin, English, and Proto-Indo-European was mirrored by that of Kolami, Telugu, and Proto-Dravidian. In many ways, his *magum opus,* the co-authored *Dravidian etymological dictionary* (Burrow and Emeneau, 1984), capped a long and as yet unfinished distinguished career.

Emotion: Stylistic Approaches

M Burke, Roosevelt Academy, Middelburg, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The concept of emotion has always played a meaningful role in stylistics, whether it be in the context of production on the part of the writer, or reception on the part of the reader. The term 'emotive,' when employed in a stylistic framework, is often used interchangeably with the term 'affective.' This is in contrast to mainstream cognitive psychology, where 'emotion' usually refers to an intense, brief moment of felt experience, while 'affect' tends to be used as a more general term (see, e.g., Frijda, 1986). An example of this interchangeability in stylistics can be seen in the notions of 'affective meaning' and 'emotive meaning,' both of which refer to the effects that highly charged words – like 'home' and 'mother' – can evoke in a reader or listener.

The roots of stylistics-related affective criticism can be traced back to classical times. Aristotle's celebrated theory of catharsis, i.e., the purging or cleansing of emotion from the body, can be said to be one of the first physiological, reception-based accounts of literary emotion. The modern history of emotion in stylistics-oriented criticism began in the 1940s and 1950s. In this period, the New Critics opposed all subjective approaches to literary criticism. Wimsatt and Beardsley (1954), in particular, highlighted what they saw as the inappropriateness of attempting to evaluate literature by its emotive effect on readers with their theory of 'the affective fallacy.' The New Critics, therefore, essentially espoused an objective view toward literary interpretation and reception that by its very nature had to exclude emotion as a factor in receptive processes. Such antisubjective views are widely viewed these days as implausible, owing to what is now known about the crucial role that top-down processing also plays in reading procedures.

The text-based formalism set out in the work of the New Critics was continued in similar ways by Jakobson (1960). Jakobson's ideas relied on formal linguistic criteria in identifying stylistic patterns in texts. His famous 'speech event,' for example, included six categories, none of which concerned emotion. However, in addition to describing those six constituents of communication, he also identified six corresponding functions, one of which was 'the emotive function.' This emotive capacity, also often called 'the expressive function,' referred to the emotive role of language that communicates the addresser's emotions and attitudes. Jakobson, therefore, did not exclude emotion as a relevant factor in human communication. However, it is important to note that his account of emotive discourse communication was centrally concerned with production rather than reception.

This changed in the 1970s and early 1980s, when emotion became an important factor in stylistics-oriented criticism. This was especially the case in some of the reader-response theories of the time. The study of emotion in stylistics switched from that produced by writers to that experienced by readers, even if these readers initially were theoretically constructed ones rather than real readers. A main figure in this period was Fish (1980), who was not interested in just the physiological aspects of emotive response, such as those that classical catharsis professes, but also in the mental or cognitive aspects of such responses in stylistics. The main tenets of Fish's 'affective stylistics,' as it was called, involved a rejection of the pure Jakobsonian author-based textualism, in favor of reader involvement. This affective approach viewed stylistic effects as being in the reader rather than in the text. Fish's affective approach to stylistics, therefore, involved a theoretical account of interpretative processes, assumptions, and expectations on the part of the reader. However, for all the advantages of Fish's affective stylistics, it can be said that it was not primarily concerned with either real emotion or real affect. Rather, it was more focused on the role that context, in general, plays in the literary interpretative process.

For quite a while after Fish wrote about affective stylistics, emotion did not play a prominent role in stylistic analysis. This is surprising, given that the study of emotion and affective language was gaining popularity in the sister disciplines of functional linguistics and discourse analysis, two areas from which stylistics traditionally takes its cues. In Hallidayan systemic functional linguistics, for example, feeling played a role in the 'mental' category of Halliday's 'grammar of experience,' together with thinking and seeing (see Halliday, 1994: 108). Additionally, it also played a part in Halliday's ideational metafunction of language (see, e.g., Wales, 2001: 195).

Likewise, in discourse analysis, emotion was, and indeed still is, viewed as a key communicative concept. The expression of feeling and attitudes is deemed to be a significant component in both verbal and written communication, especially within a framework of subjectivity and interpersonal discourse functions. One such component is the phenomenon of 'intensity markers,' which can be

defined as affective linguistic devices. Quirk *et al.* (1985) listed these words in three groups in their chapter on adverbials. These groups are 'downtoners,' or 'hedges,' 'emphasizers,' and 'amplifiers.' Additionally, intensity markers can also include verbs, adjectives, and adverbials that encode the speaker's emotions, feelings, moods, and general dispositions (for an interesting discussion on this, see Georgakopoulou and Goutsos, 1997: 137–139). In addition to intensity markers, there is also the phenomenon of 'involvement strategies,' initially developed by Chafe (1982) in his work on discourse types. Chafe listed a number of categories that show how speakers can enthrall their readers and affect their inner states by means of language. This includes such notions as 'detail and imagery,' 'first and second person pronouns,' 'action and agents,' 'hedges,' 'direct speech,' and 'aggravated signals.' Chafe's emotive work has since been developed and expanded on by Tannen (1989).

In addition to intensity markers and involvement strategies, there is also the phenomenon of 'performance features' (Wolfson, 1982), which includes 'expressive sounds,' 'motions and gestures,' 'repetition,' 'direct speech,' 'the historic present,' and 'asides.' There are also Polanyi's 'evaluation devices,' which include 'negation,' 'repetition,' 'character speech,' and 'an account of the mental and emotive states of characters' (1985). Other important emotive issues in discourse analysis concern Caffi and Janney's more recent discussion on 'affective keys' (1994) and Biber and Finnegan's notion of 'affective stance' (1988). The latter concept refers to the use of both speech and language to convey all kinds of personal feelings and judgments with regard to the particular proposition being expressed at that moment.

These are just some of the many affective linguistic concepts that are currently helping to move emotion toward the center ground of discourse studies. All of these emotive theories, however, have yet to be picked up in any systematic way in stylistic scholarship. One exception is Watson's recent stylistic-emotive study on quantitative approaches to evidentiality and affect (1999), which took Biber and Finnegan's revised version of their basic model of stance and applied it to a corpus of prose fiction. Watson concluded that Biber and Finnegan's model was indeed useful for extracting broad stylistic trends of evidentiality and affect. Although the study was informative and thorough, one might question Watson's use of solely empirical methods to investigate such essentially subjective linguistic phenomena in stylistics.

In addition to functional and discourse approaches to language, emotion is also starting to play an increasingly important role in cognitive linguistics, which, like the above-mentioned sister fields, has had an influential effect on mainstream stylistics with regard to the application of frameworks and models. A general tenet in cognitive linguistics, set out in the work of cognitive grammarian Langacker, is that meaning is comparable to conceptualization and that both rely heavily on the immediately physical and cerebral context of human emotion (1991: 2–4). An interesting cognitive development that has breathed new impetus into the role that emotion plays in stylistics is 'schema theory.' This work has come not directly from cognitive linguistics but rather from relatively recent work done in cognitive psychology (see, e.g., Rumelhart, 1975), which was influenced by the early Gestalt psychology of the 1920s. It has also been reignited by research done in artificial intelligence (see, e.g., Schank and Abelson 1977). In light of these developments, it is logical that any meaningful discussion on cognition in the 1990s could not have ignored the increasing importance of the role that emotion must play in cognitive processes. It is in this way that emotion has found a new road into stylistic approaches. This has been shown, for example, in the stylistic schema theory work of Semino (1997). In that work, Semino took Schank's purely cognitive theory of Thematic Organization Points (TOPs) and incorporated into her analyses an additional category of 'emotional associations' (see Schank, 1982). This addition reflected the necessity of accounting for the affective components in the cognitive processing of text, literary text in particular. This is without doubt one of the most important emotive additions to cognitive stylistic approaches thus far.

Stylistic work done on schema theory also has links to the broader category of what might termed 'cognitive poetics,' in which emotion often also has a central function (see especially Tsur, 1978, 1992). Emotion is also taking on an increasingly important role in cognitive stylistics, a term frequently used synonymously with cognitive poetics. Some of these recent studies include work by Gibbs (2003) on prototypes and by Burke (2001) on iconicity. Emotion has also recently been prevalent in a number of other essentially stylistic approaches. These include narrative comprehension work conducted by Emmott, especially with regard to 'character empathy' (1997) and 'foregrounding' (2002), work done on 'feeling in reading' (Stockwell, 2002), the ongoing development of a 'poetic theory of emotion' (van Peer, 1997), and the study of 'emotional and aesthetic qualities' (Tsur, 2002). There have also been some more general stylistic works published on the subject of emotion. The most significant of these is Downes's emotional, evaluative, and intuitive account of the language of

felt experience (2000). This work also crucially considers both a cultural and a cognitive dimension to emotion in the study of stylistics.

In sum, it is clear that emotion has played a meaningful yet relatively limited function in stylistic approaches over the past 30 years. However, in view of the increasingly significant role that cognition is taking, in both stylistics and the study of literary reading processes in general, it is likely that this will lead to an increase in affective frameworks and methodologies being developed and applied in future stylistic approaches. Indeed, this is something that is already discernible in many contemporary stylistic studies, as can been seen from those sketched out in the previous paragraph.

Empiricism

J Prinz, University of North Carolina, Chapel Hill, NC, USA

© 2006 Elsevier Ltd. All rights reserved.

The term 'empiricism' refers to a group of related philosophical doctrines, which place special emphasis on perception or experience. On one traditional formulation, empiricists hold that there is nothing in the intellect that is not first in the senses. This idea has roots in the texts of Aristotle and other ancient philosophers, but it was most influentially developed and defended by the British empiricists of the 17th and 18th centuries (see Locke, 1690; Hume, 1739). Empiricism took on new forms in the twentieth century. The history of Western philosophy can be usefully viewed as an extended debate between empiricists and rationalists.

Species of Empiricism

Empiricists say that experience is primary. But primary in what sense? There are several possible answers: primary as a source of knowledge; primary in the makeup of mental concepts; and primary in linguistic meaning. Each of these answers corresponds to a distinct species of empiricism. This article explains all three in turn.

In epistemology, empiricism is the doctrine that knowledge is based on experience (or '*a posteriori*'). Some epistemological empiricists claim that all knowledge is based on experience, some claim that most knowledge is, and some merely insist that the paradigm cases of knowledge are based on experience.

Historically, epistemological empiricism was contrasted with epistemological rationalism: the view that knowledge derives from intuition or pure reason. Rationalists claim that knowledge can be derived prior to experience (or '*a priori*'), and, to make good on this claim, they typically assume that we have an extensive stock of innate ideas. In ancient Greek philosophy, Aristotle and Plato inaugurated the debate between epistemological empiricists and rationalisms. Aristotle emphasized the role of observation in learning, whereas Plato emphasized innate knowledge that is acquired prior to birth and either triggered by experience (in the way that a memory might be triggered by seeing a related cue) or else revealed through philosophical reflection. In modern British philosophy, epistemological empiricism was resuscitated by Francis Bacon. Scientific method, he argued, depends on testing hypotheses against experience. Some empiricists have been willing to grant that certain domains are known *a priori*. John Locke holds this view of ethics and mathematics. Other empiricists have been more thoroughgoing. Moral sense theorists, such as Francis Hutchesen, postulate a special faculty that uses the passions – a kind of sense – to detect ethical truths. Empiricists about mathematics claim that we obtain mathematic knowledge by observation. It has been claimed that we can observe basic truths of geometry, arithmetic, and even set theory.

Epistemological empiricists typically endorse both a causal thesis and a normative thesis. According to the causal thesis, knowledge is causally obtained through experience. For example, Hume says that we obtain knowledge by association: We associate ideas of things that are experienced in spatial or temporal proximity. Associationism exerted an influence on behaviorism and connectionism. Behaviorists say we obtain knowledge by conditioning, which occurs when a stimulus or emitted behavior is accompanied by a behavioral reinforcer. Connectionists believe that knowledge acquisition involves the modulation of weighted connections between layered populations of neurons.

The normative thesis endorsed by epistemological empiricists says that experience is the primary source of epistemic justification. This thesis has often taken the form of epistemic foundationalism: the idea that knowledge must always be justified with reference to things that can be known directly. According to some foundationalists, the only things that we know directly are sense data: perceptual experiences given to us when our sense organs are stimulated (Ayer, 1936). Knowledge that goes beyond direct experience must be based on sense data. For example, Bertrand Russell (1912) argued that we obtain knowledge of the external world by inductive inference: We postulate a mind independent reality because it offers the best explanation of the fact that sense data seem to be outside our control. We might experience the shape of a cat, and then turn away, only to find that the shape remains when we return our gaze to the original position. The best explanation of this is that there is a cat in that location and it exists even when we are not viewing it. Some empiricists, who grant that all knowledge must be sense-based, find this argument unpersuasive; they are driven to skepticism about the external world or to the view that the external world is nothing but a collection of ideas (a view known as idealism or phenomenalism).

Epistemological empiricists need not be foundationalists. W. V. O. Quine (1951) claimed that theories must be confirmed against experience in entirety, rather than confirming a privileged class of

observational judgments and deriving the rest from those. Quine's alternative to foundationalism is called confirmation holism. On this approach, a judgment gains its epistemic warrant from experience along with its coherence with all the other judgments that have been supported by experience and pragmatic rules guiding theory revision. William James and John Dewey also defended versions of epistemological empiricism without foundationalism.

Epistemological empiricism can be distinguished from concept empiricism, the view that all of our concepts (or 'ideas') are derived from percepts (or 'impressions'). Ideas are encoded in the representational formats that are used by the senses. Aristotle said there is no idea without an image. John Locke and David Hume argued that ideas are abstracted or copied from impressions. This doctrine has had a recent revival in cognitive science (see Barsalou, 1999; Prinz, 2002). In addition to our external senses, concept empiricists admit that we can form ideas on the basis of 'reflection,' or inner experiences, such as the passions and sentiments. For example, Hume tried to explicate the concept of moral goodness by appeal to the sentiment of approbation.

Concept empiricists typically reject the rationalists' contention that many ideas are innate. Instead, ideas derive from 'impressions' (the mental states caused in our senses when we perceive the world). According to Locke, some ideas are simply stored copies of impressions, some are combinations of impressions, and some are derived from impressions through abstraction: a process (or set of processes) by which we extract general ideas from experiences of particulars.

In addition to epistemological and concept empiricism, there is an empiricist doctrine relating to meaning. Semantic empiricists contend that the meaning of every linguistic expression must be specifiable using expressions that ultimately get their meaning from experience. One version of this view is the principle of verifiability, which was defended by the logical positivists in the beginning of the twentieth century. According to this principle, a sentence is meaningful only if it can be confirmed or falsified by experience. All meaningful sentences use expressions that refer to things that can be directly observed (observation terms) or things that can be inferred from observable things (theoretical terms).

They allowed one kind of exception, however. The positivists drew a distinction between sentences that can be confirmed by experience (synthetic truths) and sentences that are true in virtue of the meanings of their terms (analytic truths). The sentence 'all mothers are female' is analytic, because 'mother' means female parent. The sentence 'Madonna is a mother' is synthetic. Analytic truths are, in a sense, knowable *a priori*, but they need not violate the spirit of epistemological empiricism. Analytic truths are based on relations between words that are stipulated by the authors of a language. To accept *a priori* knowledge of such truths is not a concession to the rationalists' claim that we have *a priori* access to substantive truths about the world. Nevertheless some epistemological empiricists reject analytic truths. Quine famously argued that no truth is immune from empirical refutation. New discoveries or events can lead us to revise apparent tautologies. If cross-dressing men began to adopt children and conform to prototypical maternal roles, then we might begin to refer to them as 'mothers.' Thus, 'all mothers are female' would be refuted.

These forms of empiricism often have been defended as a package, but they are independent. For example, an epistemological empiricist might reject concept empiricism and instead adopt the view that concepts are couched in a nonsensory language of thought. A concept empiricist might reject epistemological empiricism and argue for a coherentist theory of justification instead of foundationalism. Concept empiricists and epistemological empiricists might replace semantic empiricism with a causal theory of meaning, which would allow reference to unobservable entities.

Empiricism and Language

Each empiricist doctrine has implications for the study of language. This is most obvious in the case of semantic empiricism, which is a thesis about linguistic meaning. The link between epistemological empiricism and language is most remote, because theories of justification are usually held to be independent of theories of meaning. For verificationists, however, these two dimensions collapse, because meanings are equated with conditions for obtaining knowledge. Some verificationists were led by epistemological considerations (the impossibility of confirming entities hidden from view) to their thesis about meaning.

The connection between concept empiricism and language depends on the relationship between concepts and meanings. Some authors believe that concepts are private mental representations and that meanings are either mind-independent properties and propositions or public rules of linguistic behavior. Other authors believe that meanings are at least partially constituted by the concepts in our heads. Those in this latter camp would claim that an empiricist theory of concepts entails a form of empiricism about semantics. Concept empiricism would entail that meanings are at least partially constituted by perceptually derived mental representations.

Some cognitive scientists try to bridge concept empiricism and semantic empiricism by collecting evidence that people spontaneously use perceptual representations when understanding words and phrases (see, e.g., Barsalou, 1999). A related synthesis can be found in the work of some cognitive grammarians. They argue that some meanings are based on conceptual knowledge and that some concepts are partially constituted by image schemas. Image schemas are schematic (i.e., nonmetric) representations of spatial relations that are used in perceiving the world. George Lakoff (1987) has argued that highly abstract concepts, which are believed to pose a challenge for empiricists, are understood by means of metaphorical extension from perceivable spatial relations. The concept of ownership, for example, is understood with reference to the relation of spatial containment.

Some concept empiricists explain our mastery of abstract concepts in a different way. They argue that public language can be used as vehicles of thought. Sentences are observable. If concepts are stored records of experiences, they can be stored records of experiences with public linguistic items. To understand an abstract concept, on this approach, is to master a set of verbal entailments. Benjamin Whorf and Edward Sapir may have been led to their hypothesis of linguistic relativity in virtue of accepting a picture like this.

Another topic of concern to empiricists is language acquisition. Because empiricists traditionally reject innate ideas, some have argued that language can be acquired using general-purpose perceptual learning rules (such as pattern recognition, association, and conditioning). This view is highly controversial. Noam Chomsky and his followers have developed powerful arguments for the conclusion that language acquisition requires innate learning mechanisms that are specifically designed for language. Chomsky is a self-proclaimed rationalist, and some empiricists hope to prove that his arguments are mistaken.

In sum, empiricism is a family of doctrines united by the central role they afford to experience. These doctrines often have been defended by the same authors, but they are actually independent. Each has several forms, each faces different challenges, and each has implications for the nature of language.

Empty Names

B Caplan, University of Manitoba, Winnipeg, Canada

© 2006 Elsevier Ltd. All rights reserved.

Most names refer. For example, the name 'Uma Thurman' refers to Uma Thurman. But some names don't refer. For example, suppose that Keanu Reeves introduces the name 'Sparkie' to refer to the lighter in his pocket, if there is one, and to nothing otherwise. If it turns out that Keanu's pockets are empty, then 'Sparkie' doesn't refer. In that case, 'Sparkie' is an *empty name*. Usually, an empty name is empty because there is no object for it to refer to. This is the case with 'Sparkie': 'Sparkie' is empty because Keanu's pockets are empty. But sometimes an empty name is empty not because there is no object for it to refer to but rather because of something else: the speaker's intentions, say. For example, some philosophers think that although fictional characters exist, names from fiction are empty when they are used with the intention of telling a story. On this view, there is a fictional character that ***we*** can use the name 'Sherlock Holmes' to refer to when we intend to talk about Sir Arthur Conan Doyle's work, but when ***Conan Doyle*** uses that name to tell a story, it's empty.

Some cognitive scientists try to bridge concept empiricism and semantic empiricism by collecting evidence that people spontaneously use perceptual representations when understanding words and phrases (see, e.g., Barsalou, 1999). A related synthesis can be found in the work of some cognitive grammarians. They argue that some meanings are based on conceptual knowledge and that some concepts are partially constituted by image schemas. Image schemas are schematic (i.e., nonmetric) representations of spatial relations that are used in perceiving the world. Empty Names

B Caplan, University of Manitoba, Winnipeg, Canada

© 2006 Elsevier Ltd. All rights reserved.

Most names refer. For example, the name 'Uma Thurman' refers to Uma Thurman. But some names don't refer. For example, suppose that Keanu Reeves introduces the name 'Sparkie' to refer to the lighter in his pocket, if there is one, and to nothing otherwise. If it turns out that Keanu's pockets are empty, then 'Sparkie' doesn't refer. In that case, 'Sparkie' is an *empty name*. Usually, an empty name is empty because there is no object for it to refer to. This is the case with 'Sparkie': 'Sparkie' is empty because Keanu's pockets are empty. But sometimes an empty name is empty not because there is no object for it to refer to but rather because of something else: the speaker's intentions, say. For example, some philosophers think that although fictional characters exist, names from fiction are empty when they are used with the intention of telling a story. On this view, there is a fictional character that ***we*** can use the name 'Sherlock Holmes' to refer to when we intend to talk about Sir Arthur Conan Doyle's work, but when ***Conan Doyle*** uses that name to tell a story, it's empty.

The term 'empty name' goes back at least to the German mathematician and philosopher Gottlob Frege (1848–1925), who called expressions that don't refer 'empty' (or, in German, '*leer*'). The problems that empty names pose go back much further, at least to the Greek philosopher Parmenides (5th century B.C.E.), who argued that you cannot say of what does not exist that it does not exist. Empty names have been giving philosophers headaches ever since.

The Problem of Negative Existentials

Consider a subject-predicate sentence of the form ⌜$\alpha\ \varphi$⌝, where α is the subject and φ is the predicate. ⌜$\alpha\ \varphi$⌝ says, of the object that α refers to, that it has the property that φ refers to. And ⌜$\alpha\ \varphi$⌝ is true if and only if what it says is the case: that is, if and only if that object has that property. For example, (1) says, of the object (or, in this case, person) that 'Uma' refers to, that it has the property that 'is a movie star' refers to.

(1) Uma is a movie star.

'Uma' refers to Uma, and 'is a movie star' refers to the property *being a movie star*. So (1) says, of Uma, that she has the property *being a movie star*. Since Uma has that property, (1) is true. Now consider (2), which says, of the object that 'Sparkie' refers to, that it has the property that 'doesn't exist' refers to.

(2) Sparkie doesn't exist.

The predicate 'doesn't exist' refers to the property *not existing* (or *being nonexistent*). (2) is a *negative existential*, since it appears to say of some object that it doesn't exist. The trouble with negative existentials is that some of them seem true; but it's hard to see how any of them could be. For example, (2) seems true. But since 'Sparkie' is empty, there is no object that it refers to; so there is no object for (2) to say, of it, that it has the property *not existing*. As a result, it is hard to see what, if anything, (2) says. And if (2) doesn't say anything, then it is hard to see how it could be true.

More generally, negative existentials are a problem for anyone who thinks that (a) the truth value of a sentence is determined, compositionally, on the basis of some semantic feature or features of its parts, and (b) the relevant semantic feature of a name is its referent. (And many philosophers share these assumptions: for example, Fregeans, Millians, and Davidsonians all can accept [a] and [b].) Since an empty name has no referent, it seems to follow that negative existentials that contain empty names have no truth value. This is a problem, because such negative existentials seem true.

Millianism

Empty names pose a number of problems in particular for Millianism. According to Millianism, sentences express *propositions*. These are abstract objects that are the primary bearers of truth values. They are also the objects of attitudes, such as believing and asserting. According to Millianism, propositions are *structured*. This means that the proposition expressed by (1), for example, can be represented as the ordered pair <U, *being a movie star*>, where U is something that corresponds to 'Uma.' (In what follows, complications about what goes in the non-U slot are glossed over; it is assumed that what goes in that slot is a property.) And, according to Millianism, sentences that contain names express ***singular*** propositions if they express any propositions at all. This means that, in the proposition expressed by (1), U is Uma herself. The proposition expressed by (1) can then be represented as <Uma, *being a movie star*>.

The source of the problems that empty names pose for Millianism is that it seems that Millianism entails that a sentence that contains an empty name doesn't express any proposition at all. According to Millianism, propositions are structured; so, if (2) expresses a proposition, then that proposition can be represented as <S, *not existing*>, where S is something that corresponds to 'Sparkie.' And, according to Millianism, sentences that contain names express singular propositions, if they express any propositions at all; so, if (2) expresses a proposition that can be represented as <S, *not existing*>, then S is the object that 'Sparkie' refers to. But, since 'Sparkie' is empty, there is no object that it refers to. So there is no object in the S slot in <S, *not existing*>. As a result, it seems that there is no singular proposition for (2) to express and hence that, according to Millianism, (2) doesn't express any proposition at all. The view that sentences that contain empty names don't express any proposition at all is called the *No Proposition View*.

The No Proposition View apparently has a number of consequences that are apparently counterintuitive. For example, you might think that a sentence is meaningful only if it expresses a proposition. If that's right, then the No Proposition View entails that (2), for example, is meaningless. But (2) doesn't seem meaningless. This problem is called the *Problem of Meaningfulness*. Or you might think that a sentence inherits its truth value from the proposition it expresses. If that's right, then the No Proposition View entails that, for example, (2) and (3) have no truth value.

(3) Keanu believes that Sparkie doesn't exist.

But (2) and (3) seem true. This problem is called the *Problem of Truth Value*. Or you might think that a person can sincerely and assertively utter a sentence only if she believes the proposition that it expresses. If that's right, then the No Proposition View entails that no one can sincerely and assertively utter (2), for example. But it seems that someone could sincerely and assertively utter (2). This problem is called the *Problem of Belief and Sincere Assertive Utterance*. Because of these problems (and others that have to do with the substitution of coreferential names in various linguistic contexts), many philosophers have concluded that Millianism should be rejected in favor of its rival, Fregeanism.

Fregeanism

Fregeanism can solve many of the problems that empty names pose for Millianism. Fregeanism agrees with Millianism that sentences express structured propositions. According to Fregeanism and Millianism alike, the proposition expressed by (1) can be represented as <U, *being a movie star*> (again, glossing over what goes in the non-U slot). But Fregeanism denies that sentences that contain names express singular propositions. According to Fregeanism, in the proposition expressed by (1), U is ***not*** Uma herself. Rather, U is a *mode of presentation* of Uma, $MP_{\text{'Uma'}}$, something that is a way of thinking about Uma or that captures an agent's perspective on Uma. Perhaps $MP_{\text{'Uma'}}$ is something that picks Uma out by describing her as having certain properties: *being the lead in Kill Bill Vol. 1*, say. Or perhaps $MP_{\text{'Uma'}}$ is some other kind of entity. Where Millians say that the proposition represented as <Uma, *being a movie star*> is true if and only if Uma has the property *being a movie star*, Fregeans say that the proposition represented as <$MP_{\text{'Uma'}}$, *being a movie star*> is true if and only if the object that $MP_{\text{'Uma'}}$ presents has the property *being a movie star*. Since $MP_{\text{'Uma'}}$ presents Uma, Fregeans agree with Millians that the proposition that (1) expresses is true if and only if Uma has the property *being a movie star*.

Fregeans can reject the No Proposition View. According to Fregeanism, the proposition expressed by (2) can be represented as <S, *not existing*>. But, according to Fregeanism, S isn't the object that 'Sparkie' refers to; rather, S is a mode of presentation, $MP_{\text{'Sparkie'}}$, that corresponds to 'Sparkie.' (If there is such a mode of presentation, then there can be empty modes of presentation: that is, modes of presentation that don't actually present anything. But *see* **Object-Dependent Thoughts**.) Perhaps $MP_{\text{'Sparkie'}}$ has something to do with the property *being a lighter in Keanu's pocket* and would pick out the unique object that has that property, if there were such an object. Or perhaps $MP_{\text{'Sparkie'}}$ is some other kind of entity.

Fregeans can solve the Problem of Meaningfulness: (2) is meaningful because it expresses the proposition represented as <$MP_{\text{'Sparkie'}}$, *not existing*>. Fregeans can also solve the Problem of Truth Value, at least for belief ascriptions like (3). (3) can be true because Keanu can believe the proposition represented as <$MP_{\text{'Sparkie'}}$, *not existing*>. (How the truth of [3] can be compatible with the assumptions [a] and [b] mentioned earlier is complicated. Perhaps in [3] 'Sparkie' isn't really empty: perhaps in [3] Sparkie refers to $MP_{\text{'Sparkie'}}$. Or perhaps in [3] 'that' refers to the proposition that [2] expresses.) And Fregeans can solve the Problem of Belief and Sincere Assertive Utterance: speakers can sincerely and assertively utter (2) because they can believe the proposition represented as <$MP_{\text{'Sparkie'}}$, not existing>.

But Fregeanism doesn't straightforwardly solve the Problem of Truth Value for sentences like (2). For (2) is true if and only if the proposition that it expresses, the proposition represented as <$MP_{\text{'Sparkie'}}$, *not existing*>, is true; and that proposition is true if and only if the object that $MP_{\text{'Sparkie'}}$ presents has the property *not existing*. But there is no object that $MP_{\text{'Sparkie'}}$ presents, and hence it is not the case that the object that $MP_{\text{'Sparkie'}}$ presents has the property *not existing*. So (2) isn't true. Still, many philosophers think that overall Fregeanism fares better than Millianism in handling the problems that empty names pose.

More Millianism: The Gappy Proposition View

Some Millians reject the No Proposition View in favor of the *Gappy Proposition View*, according to which (2) expresses a *gappy proposition* that can be represented as <____, *not existing*>. (That proposition is gappy because it is just like a singular proposition except that it contains no object where a singular proposition would.) The Gappy Proposition View can solve the Problem of Meaningfulness: (2) is meaningful because it expresses the gappy proposition represented as <____, *not existing*>. The Gappy Proposition View can also solve the Problem of Truth Value, at least for belief ascriptions like (3). (3) can be true because Keanu can believe the proposition represented as <____, *not existing*>. And the Gappy Proposition View can solve the Problem of Belief and Sincere Assertive Utterance: speakers can sincerely and assertively utter (2) because they can believe the proposition represented as <____, *not existing*>.

But the Gappy Proposition View can't solve the Problem of Truth Value in general. Suppose that Uma introduces 'Markie' to refer to the pen in her pocket, if there is one, and to nothing otherwise. If it turns out that Uma's pockets are empty, too, then 'Markie' doesn't refer either. On the Gappy Proposition View, (4) and (5) express the same gappy proposition, which is a conditional whose antecedent can be represented as <____, *existing*>.

(4) If Sparkie exists, then there is a lighter in Keanu's pocket.

(5) If Markie exists, then there is a lighter in Keanu's pocket.

But (4) and (5) seems to differ in truth value: (4) seems true, whereas (5) doesn't.

Millians could co-opt some of the resources of Fregeanism and say that agents believe propositions via modes of presentation. (4) and (5) express the same gappy proposition; but there are different modes of presentation associated with (4) and (5). The mode of presentation associated with (4) has something to do with $MP_{\text{'Sparkie'}}$, whereas the mode of presentation associated with (5) has something to do with $MP_{\text{'Markie'}}$. On this view, (4) seems true, because agents believe, via the mode of presentation associated with (4), the gappy proposition expressed by (4) and (5); but (5) doesn't seem true, because agents don't believe that proposition via the mode of presentation associated with (5). Let's call a Millian view that co-opts Fregean resources in some way *Neo-Millian*.

Still More Millianism: The Communicated Proposition View

Once Millians co-opt Fregean resources and become Neo-Millians, they no longer have to appeal to gappy propositions. Neo-Millians can say that ***sentences*** that contain empty names don't ***express*** propositions; but when they use those sentences, ***speakers*** can ***communicate*** propositions and in fact speakers can communicate the very propositions that Fregeans say are expressed by the sentences that speakers use. Let's call this view the *Communicated Proposition View*. The Communicated Proposition View can solve the Problem of Meaningfulness: (2) is meaningful because speakers can use it to communicate the proposition represented as <$MP_{\text{'Sparkie'}}$, *not existing*>. The Communicated Proposition View can also solve the Problem of Truth Value: (2) seems true because speakers use it to communicate the proposition represented as <$MP_{\text{'Sparkie'}}$, *not existing*>; and (3) seems true because speakers use it to communicate that Keanu believes that proposition. And the Communicated Proposition View can solve the Problem of Belief and Sincere Assertive Utterance: speakers can sincerely and assertively utter (2) because they can believe the proposition represented as <$MP_{\text{'Sparkie'}}$, *not existing*>.

The possibility of Neo-Millianism suggests that the debate between Millians (including Neo-Millians) and Fregeans should be understood not as a debate about ***whether*** there are modes of presentations like $MP_{\text{'Sparkie'}}$ but rather as a debate about ***where*** there are such modes of presentation. Fregeans says that such modes of presentation are constituents of the propositions expressed by sentences that contain names. Millians, by contrast, say that they're not, although they might mediate agents' cognitive relations to propositions (as on the Neo-Millian version of the Gappy Proposition View) or they might be constituents of propositions that speakers communicate (as on the Communicated Proposition View).

Encyclopédie

N E Cronk

© 2006 Elsevier Ltd. All rights reserved.

This work of 20 million words is both the greaest summa of the French Enlightenment and its greatest manifesto. It symbolizes the 18th century's crusade against superstition, fanaticism, and tyranny, and its belief in human progress, happiness, and freedom. The articles and accompanying plates also constitute an unrivaled source of information about the scientific and technological knowledge of the period.

The History of the Work

An initial project to translate Chambers' two-volume *Cyclopaedia* (1728) grew into the much more ambitious *Encyclopédie ou Dictionnaire raisonné des Sciences, des Arts et des Mêtíers, par une société de gens de lettres*. The work appeared between 1751 and 1772, in 28 folio volumes, 17 of text and 11 of plates, during which time the two editors D'Alembert and Diderot (*see* **Diderot, Denis (1713–84)**) – Diderot alone, after the defection of D'Alembert in 1757 – endured continual struggles with the authorities. The 71 818 articles are written by more than 200 different authors, ranging from Voltaire and Rousseau to the unknown and the anonymous.

The work's influence was widespread and enduring. The first edition of 4225 copies quickly sold out, and several further editions followed, some published outside France, some in smaller formats. By the end of the 18th century there were some 24 000 copies of the *Encyclopédie* in circulation, over half of them outside France.

The Range of the Work

The sheer size of the *Encyclopédie* makes it difficult for the reader to form a balanced overall impression of the work. The selections of essays by which modern readers generally know the *Encyclopèdie* give a distorted view by concentrating on articles concerned with religion and politics. These were certainly among the most controversial contributions, but they are neither the most typical nor, necessarily, the most radical.

One of the most original aspects of the *Encyclopédie* is the considerable emphasis given to manufacture and technology: Diderot himself opted to write the article *Bas* on the manufacture of stockings. The unsigned article *Christianisme* (Christianity) is subversive not so much because it expresses unorthodox views (although it does), as because under the letter 'C' it is equated with, and outnumbered by, such other articles as *Chaise* (Chair), *Chandelle* (Candle), *Chanvre* (Hemp), *Chapeau* (Hat), and *Charbon* (Coal).

Another important and highly original feature is the emphasis accorded to the image. The 2900 engraved plates, magnificent documents in their own right, are conceived as an essential complement to the articles. The plates accompanying the technological articles are also of linguistic importance, for they record, often for the first time, the terms employed by artisans to describe tools and machineparts.

Language and grammar are accorded an important place, and there are articles on such questions as grammatical terminology, the origin of language, and spelling reform. The grammatical articles of Dumarsais were particularly praised, and after his death in 1756, major articles were contributed by Douchet, author of *Grammaire* (Grammar), and Beauzée, author of the long article *Langue* (Language). Many articles (including some by Diderot) are devoted to the definition of synonymous or near-synonymous terms. The Cartesian emphasis (*see* **Descartes, René (1596–1650)**) on clarity of language as a first step towards clarity of thought is central to the encyclopedists' project: "It is still not understood," writes Diderot (in the article *Encyclopédie*, 'Encyclopedia'), "to what extent language is a rigorous and faithful image of the exercise of reason."

The Personality of the Work

Notwithstanding their concern with clarity of expression, the encyclopedists were obliged for political reasons to resort to various strategies of concealment. The brief and apparently innocuous grammatical

This work of 20 million words is both the greaest summa of the French Enlightenment and its greatest manifesto. It symbolizes the 18th century's crusade against superstition, fanaticism, and tyranny, and its belief in human progress, happiness, and freedom. The articles and accompanying plates also constitute an unrivaled source of information about the scientific and technological knowledge of the period.

The History of the Work

An initial project to translate Chambers' two-volume *Cyclopaedia* (1728) grew into the much more ambitious *Encyclopédie ou Dictionnaire raisonné des Sciences, des Arts et des Mêtíers, par une société de gens de lettres*. The work appeared between 1751 and 1772, in 28 folio volumes, 17 of text and 11 of plates, during which time the two editors D'Alembert and Diderot (*see* **Diderot, Denis (1713–84)**) – Diderot alone, after the defection of D'Alembert in 1757 – endured continual struggles with the authorities. The 71 818 articles are written by more than 200 different authors, ranging from Voltaire and Rousseau to the unknown and the anonymous.

The work's influence was widespread and enduring. The first edition of 4225 copies quickly sold out, and several further editions followed, some published outside France, some in smaller formats. By the end of the 18th century there were some 24 000 copies of the *Encyclopédie* in circulation, over half of them outside France.

The Range of the Work

The sheer size of the *Encyclopédie* makes it difficult for the reader to form a balanced overall impression of the work. The selections of essays by which modern readers generally know the *Encyclopèdie* give a distorted view by concentrating on articles concerned with religion and politics. These were certainly among the most controversial contributions, but they are neither the most typical nor, necessarily, the most radical.

One of the most original aspects of the *Encyclopédie* is the considerable emphasis given to manufacture and technology: Diderot himself opted to write the article *Bas* on the manufacture of stockings. The unsigned article *Christianisme* (Christianity) is subversive not so much because it expresses unorthodox views (although it does), as because under the letter 'C' it is equated with, and outnumbered by, such other articles as *Chaise* (Chair), *Chandelle* (Candle), *Chanvre* (Hemp), *Chapeau* (Hat), and *Charbon* (Coal).

Another important and highly original feature is the emphasis accorded to the image. The 2900 engraved plates, magnificent documents in their own right, are conceived as an essential complement to the articles. The plates accompanying the technological articles are also of linguistic importance, for they record, often for the first time, the terms employed by artisans to describe tools and machineparts.

Language and grammar are accorded an important place, and there are articles on such questions as grammatical terminology, the origin of language, and spelling reform. The grammatical articles of Dumarsais were particularly praised, and after his death in 1756, major articles were contributed by Douchet, author of *Grammaire* (Grammar), and Beauzée, author of the long article *Langue* (Language). Many articles (including some by Diderot) are devoted to the definition of synonymous or near-synonymous terms. The Cartesian emphasis (*see* **Descartes, René (1596–1650)**) on clarity of language as a first step towards clarity of thought is central to the encyclopedists' project: "It is still not understood," writes Diderot (in the article *Encyclopédie*, 'Encyclopedia'), "to what extent language is a rigorous and faithful image of the exercise of reason."

The Personality of the Work

Notwithstanding their concern with clarity of expression, the encyclopedists were obliged for political reasons to resort to various strategies of concealment. The brief and apparently innocuous grammatical

article *Origine* (Origin), explains the word with the following example: "Modern-day religious practices almost all have their *origin* in paganism." Some of the most anodyne titles conceal expressions of the most unorthodox opinion: *Aigle* (Eagle), deftly turns discussion of the bird's mythical importance in ancient religion into an unexpected attack on Christian superstition and human gullibility: *Aius-Locutius*, an article on the Roman god of speech, turns out to be a plea for freedom of expression. Another technique is that of the subversive crossreference: the article *Cordelier* gives a perfectly neutral account of this religious order, then refers the reader back to *Capuchon*, in which all religious orders are violently attacked.

Humor and surprise need not be polemical. The article *Langres*, written by Diderot about his home town, unexpectedly and charmingly takes an autobiographical turn. Diderot's article *Aguaxima* is essential reading for all users (and writers) of encyclopedias: What is the point, he asks, of writing an article on a Brazilian plant about which nothing is known save its name? "If I even mention it, it is out of deference to those readers who prefer to find nothing in a dictionary article, or even pure nonsense, rather than find no article at all."

The Humanity of the Work

In the article *Encyclopédie*, Diderot defines an encyclopedia as "a brief and disinterested exposition of men's discoveries in all places, in all disciplines, and in all centuries"; later he declares the aim of the present work to be "to change the general way of thinking." Some commentators have seen an inconsistency between the *Encyclopédie*'s status as a work of reference, and the clearly polemical intentions of its editors. This is to misunderstand both the *Encyclopédie* and the Enlightenment. The attempt to marshal alphabetically all human knowledge was an intrinsically polemical gesture, since it challenged head-on the prevailing ideology in which theology was the pivotal discipline. The encyclopedists advocate a different (bourgeois) ideology according to which secular human reason is the assumed starting-point of all inquiry. The universe without man is nothing, writes Diderot (*Encyclopédie*): "Why should we not accord man in our work the same place which he occupies in the universe? Why should we not place him at the centre of both?"

Language Endangerment

Although it is somewhat difficult to count languages and to measure linguistic diversity with exact precision, there are an estimated 6800 languages spoken in the world today. While there is some question as to exactly how many languages will be lost over the course of this century – ranging from a low of 25% to a high of 90% – there is widespread agreement that language loss is occurring at an unprecedented rate. Most recent studies have concluded that at least 50% of the world's languages are losing speakers and that by the end of this century, a full 90% of the world's languages will disappear entirely, replaced by more widely used (national and/or global) languages. This situation is generally referred to as language endangerment, a term used broadly for languages which are threatened with absolute loss; a language is considered lost when it has no speakers. Language endangerment is sometimes called language attrition or language death, but 'death' is avoided out of sensitivity to the population whose language has been lost. Language attrition and moribundity – when children cease learning a language – are now taking place with exceptionally rapid speed. Hundreds of languages are currently endangered and there are few parts of the world where some form of language decline is not occurring. While language attrition is not in and of itself a new phenomenon, the rate of decline in linguistic diversity appears to be unique to this era, and

is perhaps rivaled only by the kind of language loss which took place in conjunction with the agricultural revolution of approximately 10 000 years ago. One consequence is that a significant number of communities are facing the loss of a language which historically and traditionally has been foundational to their sense of identity. In some instances communities are reacting with efforts to revitalize the local language, while in others they lack the resources, time, or motivation to do so.

Linguists are particularly concerned with the loss of indigenous, or local, languages, as opposed to immigrant languages. For the latter, the language may give way in the new territory to an already established (national or dominant) language, but a robust speaker community continues/thrives in the homeland of the immigrants. (This is the situation of most immigrant languages in the United States, for example; for the most part, second-generation immigrants speak and use English in their daily lives, but their ancestral language is maintained in their original homeland. English, in contrast, is an immigrant language to North America; for a range of historical, socio-economic, and political reasons, it has largely ousted Native American local languages.) It is the loss of such local languages which is of concern to linguists, as their loss means an absolute kind of disappearance of the language. Thus, by and large, the term 'language endangerment' refers to the attrition and potential loss of local languages. A language is considered endangered when it is used by fewer speakers and when it is used in fewer situations or domains.

Language endangerment typically involves language contact situations, with two (or more) languages in use, where one language (Language A) replaces another (Language B). Prototypically, Language A is being adopted by speakers of Language B and so Language A replaces Language B in the sense that decreasing numbers of speakers of Language B use it, until ultimately there are no speakers of Language B at all. This is referred to as language shift, a term which refers specifically to such changes in patterns of language use, whereby speakers abandon the language of their parents in favor of another language. In the scenario outlined here, Language A can most neutrally be referred to as a language of wider communication; it tends to be a language which holds social prestige, serves official and governmental functions, and is used in education. It is often a regional or national lingua franca, i.e., the language which groups speaking different languages use to communicate with one another. It is also called, less neutrally, the dominant language, the majority language, or even the killer language. 'Dominant language' is to be avoided as it implies a deliberation on the part of the speakers of that language to dominate others; in some instances this is in fact the case, as when language policies intentionally restrict use of a local language. But in other situations the influence of the language of wider communication is more indirectly and subtly attained, through prestige and social pressures. Similarly, a number of labels are used to refer to Language B, such as minority language, indigenous language, mother tongue, or heritage language. The term 'local language' is more neutral and captures the fact that language use is tied to a particular geography, and that a speaker community generally sees the need or desire to use this language within a given region. The respective terms 'majority' and 'minority' for Languages A and B are not always accurate; speakers of Language B may be numerically greater but in a disadvantaged social or economic position which makes the use of the language of wider communication attractive. The term 'heritage language' can be confusing, as it is often used to refer to the language of one's ancestors, regardless of how many generations have passed since anyone spoke the language. It does not necessarily refer to a local or indigenous language, and can also refer to the ancestral languages of immigrants, even when they have not been spoken for generations.

Predications of language loss stem from several considerations, which center around a combination of critical factors in language vitality, including the number and generations of speakers, their geographic distribution and relative isolation, and recognition of ongoing rapid language shift. First, there is a very uneven distribution between languages and speakers, with just a handful of languages spoken by a very large percentage of the global population. According to current counts, approximately half the world's population speaks one of just 20 languages, and eight languages (Mandarin [Mandarin Chinese], Spanish, English, Bengali, Hindi, Portuguese, Russian, and Japanese) surpass all others with over 100 million speakers. Arabic could perhaps be added to this list: the sum total of all speakers of some form of Arabic makes it the fifth largest language, with over 200 million speakers. Not all varieties of Arabic are mutually intelligible, however, and so the differences between them are more language-like than dialect-like. Yet given the total number of people who speak some variety of Arabic, it should be included in the list of major world languages. The situation is markedly different for most of the world's languages. Some 96% of all languages are spoken by just 4% of the population, and one-fourth of the total number of languages have fewer than 1000 speakers. More than half of all languages have fewer than 10 000

speakers. Although the total number of speakers is not the sole indicator of language vitality, it is certainly a very important one. A very large majority of the world's population speaks just a very few languages. More to the point is the fact that we are witnessing rapid language shift, with a small set of major or global languages gaining in terms of numbers of speakers at the expense of a vast majority of the world's languages.

Finally, it is important to note that the geographic distribution of languages is also very uneven, with the largest numbers of languages spoken in Africa and Asia, and much smaller numbers elsewhere, such as in North and South America and the Pacific. Europe has a very few languages, both in terms of raw numbers and of percentage relative to the whole. This distribution is summarized in **Table 1**.

Distribution by continent or region is only part of the story. Language density, or the number of languages per unit area, varies greatly. Papua New Guinea stands out with 820 languages; with its relatively small territory, it has the highest language density of any country in the world. In all of North America, fewer than 200 indigenous languages remain, although there were certainly hundreds of distinct languages several centuries ago. Today, only a handful of these (such as Cree, Dakota, Ojibwa, Navajo) have a hope of survival, and even their longevity is doubtful. The case of Cree is illustrative. As of the 1998 Canadian census, there was a total of 87 555 speakers of all varieties of Cree. These speakers are not monolingual, however, and they show low literacy rates in Cree (only 5–10%) but high literacy rates in a second language, usually English (75–100%). Such figures are indicative of significant language shift. The figures for Dakota are even more alarming, with fewer than 27 000 speakers in North America as a whole, and only 31 monolingual speakers (as of 1990). Basic descriptions of Dakota speech patterns note that in some communities the children and young adults do not speak Dakota or at least prefer to speak English. Again, these are all signs of ongoing and advanced language shift, leading toward language extinction.

Table 1 Geographic distribution of languages

	Total living languages	*Percentage*
The Americas	1013	15%
Africa	2058	30%
Europe	230	3%
Asia	2197	32%
The Pacific	1311	19%
Total	6809	

Source: Grimes (2000).

As this may suggest, in only a very few cases is language loss due to the loss of the speaker population itself. Instead, the primary cause for language loss is language shift, when speakers cease to speak their own native tongue, the local language, in favor of the language of what is usually, politically and/or economically, the dominant culture. Such shift from the local to the language of wider communication can occur over several generations, or even as quickly as over the course of a single generation. In many cases the oldest generation – the grandparent group – speaks the local language as their first and primary language and has limited or nonfluent knowledge of the external language of communication; in some instances they may even have no knowledge at all of the language of wider communication. In contrast, the middle generation has some knowledge but primarily uses the language of wider communication, and the youngest generation has little to no knowledge of the local language, using at best a few words or phrases, such as greetings. In cases of rapid language shift, however, these changes occur across a single generation.

Levels of Language Endangerment

Implicit to the study of language endangerment is the notion that a relatively vital language can change to a state of endangerment at some point, usually when children cease learning the language. In studying language endangerment, it is important to assess degrees of vitality versus endangerment. That said, because a large number of factors enter into each situation, it can be difficult to rank levels of endangerment. Therefore, different linguists have proposed a variety of scales, with differing numbers of stages of endangerment and different labels for each level. There is, however, widespread agreement on the ends of the scale: safe languages and extinct languages. Generally, languages are categorized with respect to endangerment on a scale of six levels: safe, at risk, disappearing, moribund, nearly extinct and extinct.

Safe: A language is considered safe when all generations use the language in all or nearly all domains. It has a large speaker base relative to others spoken in the same region and, therefore, typically functions as the language of government, education, and commerce. Many safe languages enjoy official status within nation-states, and as such tend to be held in higher prestige than other languages.

At Risk: A language is at risk when it is vital (being learned and used by people of all different age groups)

without any observable pattern of a shrinking speaker base, but lacks some of the properties of a safe language: for example, it is spoken in a limited number of domains or has a smaller number of speakers than other languages in the same region.

Disappearing: A language is disappearing when there is an observable shift towards another language in the communities where it is spoken. With an overall decreasing proportion of intergenerational transfer, the speaker base shrinks because it is not being replenished. Disappearing languages are consequently used in a more restricted set of domains, and a language of wider communication begins to replace it in a greater percentage of homes.

Moribund: A moribund language is one that is not being transmitted to children.

Nearly Extinct: A language can be considered nearly extinct when only a handful of speakers of the oldest generation remain.

Extinct: An extinct language is one with no remaining speakers.

It should be noted that sometimes an intermediate stage between 'safe' and 'at risk' is recognized, 'safe but small,' determined by languages which are otherwise safe and stable but have a relatively small speaker base. The last three levels of language endangerment given here – moribund, nearly extinct, and extinct – are characterized by a lack of intergenerational transmission; disappearing languages are characterized by a downward trend.

Many linguists would argue that any language which is not at the safe level is endangered. Furthermore, there does not appear to be a direct correlation between the level of endangerment and the anticipated rate of language attrition: some communities shift language usage more slowly, and others more quickly. That said, language endangerment is currently a pressing concern for the linguistic community precisely because rapid attrition is occurring at a global level. In addition, the kinds of documentation and revitalization efforts needed are directly related to the level of endangerment. The closer a language is to extinction, the greater the urgency to act before fluent speakers are gone. Except in cases of sudden attrition (e.g., when a language is abruptly lost through natural catastrophe or warfare; see the next section), endangered language situations tend to be characterized by speakers of differing proficiency levels. Languages ranked at any level below safe tend to have communities which include individuals who are semispeakers, i.e., not fully fluent speakers, lacking native proficiency; the ratio of semispeakers to fluent speakers varies among communities and with endangerment levels. Such semispeakers show varying degrees of fluency, ranging from strong or nearly fluent speakers, through reasonably fluent semispeakers and weak semispeakers who are less fluent, to those with even more limited speaking competence. In assessing language vitality, it is thus important to take into consideration the proficiency and knowledge of the speakers of the language. Even in the case of extinct languages, there may be cause to move quickly, as there may still be 'rememberers' of the language who have some recollection of its use or may have some experience with it. Sometimes communities opt to resurrect (or 'resuscitate') extinct languages; rememberers can play a critical role in these efforts. Here too there is a range of proficiency: in some cases such rememberers have memorized entire texts without understanding their meaning, while the knowledge of others is restricted to only a few words or phrases. They can play an important role in language revitalization and documentation efforts, but they are static and do not represent living language.

What Is Lost?

There are a number of reasons to be concerned about language attrition. Language is a key part of each person's identity and is an essential component of a group's cultural and social heritage. Local communities who have lost their language speak about it as a deeply personal loss which is accompanied by a loss of a sense of self. Speakers whose languages are not endangered are also aware of the importance of language as a marker of identity and pay great attention to differences in dialects and speech patterns. Thus perhaps one of the most compelling reasons to be concerned about language endangerment is that the speakers who lost this part of their heritage deeply regret it and grieve over it. For this reason, so many different communities around the world are currently engaged in language revitalization efforts. Some of those groups whose languages are extinct are now attempting to resurrect them from whatever records have survived, including missionary descriptions, grammars, and sometimes oral recordings.

Loss of language also means a loss of intellectual wealth. From the linguistic standpoint, as we lose languages, we lose linguistic diversity. A great many of the world's broad array of endangered languages are understudied; what little knowledge we have indicates that many are structurally very different from the languages spoken by the majority of the global population (e.g., Mandarin, English, Spanish, and so on). The languages with the most speakers, cited in **Table 1**, represent a very small portion of the world's languages typologically and genetically.

Thus language loss means a decline in sources about the range of human language and its limitations. For the linguistic community, one of the challenges of language endangerment is to record and describe as many languages as possible while they are still spoken, so that we do not lose this wealth of human knowledge without record. Language loss should also be considered from the broader scientific perspective. Language encodes the range of human experience and knowledge; its disappearance entails the loss of the skills, information, beliefs, and ideas of a people. Often this involves specific knowledge about plants and their medicinal uses. It also includes historical knowledge; preliterate societies record their histories in their oral traditions, including stories, legends, and songs which tell the history of their people, settlements, battles, and so on. Language is more than a repository for religious and spiritual beliefs; in many societies the language itself is sacred and cannot be separated from religious beliefs and practices.

Taxonomy of Endangerment Situations

Language change and loss are naturally occurring processes which have been in place as long as language itself. Every language is constantly changing over time, and eventually evolves into one or more related but different languages; for example, the modern Romance languages (Spanish, Italian, French, and so on) are related to Latin, which is no longer used as a spoken language except for religious purposes. This kind of language 'loss' is a natural and ongoing process. Linguists are more concerned, however, with the absolute loss of language, which occurs when a language disappears entirely, without descendant languages. This kind of loss comes about in several different ways. Sometimes an entire speaker community passes away due to warfare, genocide, or disease. More frequently, however, language loss is the result of language shift, when speakers cease to speak their own native (local) tongue in favor of the language of what is usually the dominant culture, dominant politically and/or economically. The time frame for such shift varies across situations; it can take place over several generations, or much more quickly. One typical pattern is that the oldest generation, the grandparents, speaks the local language as their first and primary language, the middle generation has some knowledge but uses the dominant language primarily, and the youngest generation has little or no knowledge of the heritage language, and may at most know a few words or phrases. In cases of rapid language shift, however, these changes occur across a single generation, with the parent generation speaking the local language but their children, for whatever reasons, speaking a different one.

There are a number of ways to categorize language endangerment situations. One useful taxonomy takes into account the relative rate of attrition together with its causes. This taxonomy recognizes four different categories of attrition: sudden, radical, gradual, and top to bottom.

Sudden attrition refers to language loss which occurs abruptly because of the sudden loss of its speakers due to disease, war, natural disasters, and so on. Relatively few cases of sudden attrition have been documented, although it most probably occurred more frequently during periods of colonization, when certain indigenous groups are known to have been annihilated due to disease. In modern times, civil strife, ethnic and religious clashes, and the spread of some diseases, such as HIV, increase the chances of sudden attrition occurring in certain areas of the world.

Radical attrition is similar to sudden attrition in the sense that it comes about due to political circumstances which cause speakers to stop using their language. Such circumstances include repression and/or genocide, often occurring where groups are singled out for ethnic cleansing. (Under colonization and later, apartheid in South Africa, for example, Khoisan speakers abandoned their ethnic identity and so too their languages in order to avoid repressive measures which included genocide.) Such language shift is thus a means of self-defense or even self-preservation for speakers for whom identification with their ethnic group may lead to persecution. In these circumstances people are likely to cease speaking their heritage language abruptly.

Cases of gradual attrition are more prevalent in the world today. Gradual attrition is the relatively slow loss of a language due to language shift away from the local language to a language of wider communication. In some cases the language of wider communication is a regionally dominant language, and in others a national lingua franca. Gradual attrition often involves transitional bilingualism: as the speaker population is in the process of shift, certain groups primarily speak the local language and others the language of wider communication. Thus it is here that the clearest gradations in intergenerational transmission are to be found. Because this type of attrition is gradual, speaker communities may be unaware that it is in progress, until it is quite advanced and the local language is seriously endangered.

Bottom-to-top attrition refers to the loss of the local languages in most domains with the exception of religious and ritual practices. Languages at this

level are in an advanced stage of attrition. The local language is preserved only in those contexts where its use is seen to be the most critical. This tends to be those types of context where ritualized or sacred texts are critical, and the population may view the specific language of these as sacred in and of itself. Such ritualized or ceremonial texts are often memorized. Because these tend to be very prestigious but restricted domains for a community, it can be difficult to assess the actual vitality of the language in question. In less advanced instances of bottom-to-top attrition, the language is still used spontaneously in the settings to which it has been assigned by members of the local community. In extreme cases, the only remaining knowledge of a local language may be memorized portions of a ceremony. There are reports of communities which have retained the memorized rituals in the local language for many generations but have lost all comprehension of them.

Assessing Language Vitality

The factors involved in assessing language endangerment or vitality are complex. Language vitality is usually ranked in scalar terms on the basis of a combination of factors, in particular on numbers and generations of speakers. On one end of the scale are extinct languages which are no longer spoken at all, and on the other end are viable languages in no current threat of endangerment. In between these two extremes, a number of stages can be recognized. A healthy language with strong vitality is used with a variety of functions and in a range of settings, usually called domains. The most vital languages are used in all settings, formal and informal, official and in the home. In cases of language attrition, the local language is used in increasingly fewer domains with fewer functions as attrition progresses. Simply put, an important diagnostic in assessing vitality is the range of uses of a particular language.

Although it is often thought that the absolute number of speakers of a language is the key factor in language vitality, experts agree that in fact it is intergenerational transmission which is critical in determining it. In order for a language to be healthy, it needs to be used by future generations. When children cease learning and speaking a language, it is already endangered, even if there still exists a significant number of speakers. Intergenerational transmission does not in and of itself guarantee the safety of a language, however, as a complex set of factors are involved. These all pertain to questions of who uses the language, how, and when. In 2003 UNESCO's Ad Hoc Expert Group on Endangered Languages established a core set of nine criteria to be used in determining language endangerment:

1. Intergenerational transmission
2. Absolute number of speakers
3. Proportion of speakers within the total population
4. Trends in existing language domains
5. Response to new domains and media
6. Materials for language education and literacy
7. Governmental and institutional attitudes and policies, including official status and use
8. Community members' attitudes toward their own language
9. Amount and quality of documentation.

These nine factors are key in assessing language vitality. Variables (1)–(3) involve the distribution of speakers of the language, relative to the total number of the ethnic population as well as to generational stratification, and in absolute terms as well. Variables (4) and (5) are concerned with domains of language use; (7) and (8) with attitudes at the local and national level; and (6) and (9) are related to the kinds of material available for the language, including both pedagogical and reference materials as well as linguistic documentation. Strictly speaking, the level of linguistic documentation relates to language endangerment only insofar as ample documentation can aid language revitalization or resurrection efforts; the act of documenting a language does not directly affect its vitality.

Intergenerational Transmission

Intergenerational transmission is the single most important factor in determining a language's viability. In order for a language to remain healthy, it must be spoken by children, as they are the representatives and predecessors of future generations of speakers. For this reason, intergenerational transmission is the single most critical factor in a language's ongoing vitality. At the same time, rates of intergenerational transmission may vary between villages or speaker communities and it cannot be assumed to be uniform across a speaker population. There can be variation within a single village: it is often the case that in one family the children do not learn to speak the local language but in another they do. As this accurately suggests, overall language vitality may be uneven, higher in some communities and lower in others. A thorough analysis of language vitality requires attention to such regional variation in addition to the generational variation in transmission and use. A 10-way distinction in terms of transmission and use is proposed by Krauss (1997) to enable a more

detailed means of assessing variation in speaking patterns across generations:

a. The language is spoken by all generations, including all, or nearly all, of the children.
a-. The language is learned by all or most children.
b. The language is spoken by all adults, parental age and up, but learned by few or no children.
b-. The language is spoken by adults in their 30 s and older but not by younger parents.
c. The language is spoken only by middle-aged adults and older, in their 40 s and up.
c-. All speakers are in their 50 s and older.
-d. All speakers are in their 60 s and older.
d. All speakers are in their 70 s and older.
d-. All speakers are in their 70 s and older, and there are fewer than 10 of them.
e. The language is extinct, with no speakers.

As this scale suggests, it is important to make distinctions across age-groups within a single generation as well as across generations. Some might argue that a language is already in danger at stage (a-), when some of the children are not learning it. At stage (b), there is a greater level of danger, and so on; if the language is to survive at this stage, efforts need to be made at revitalization, or for reversing language shift. This scale may appear overly detailed; it is clear that a language is already on the way to extinction when it has reached stage (b). Yet at times it is needed. First, it can be quite useful in assessing the relative vitality not only of different languages, but at times more importantly, of various speaker communities. Inuktitut, for example, can be rated at level (a) in Greenland, where there are fluent speakers of all generations. (There are other factors which enter into its vitality in Greenland, such as official language status and use in education.) In some other Inuktitut-speaking communities, however, children are not learning the language and it is on the path to extinction. This is the case in specific communities in Canada and Alaska, although the children are acquiring it in other communities. This example further underscores the fact that evaluating the overall status of a language can be difficult, as it may vary from community to community. Second, if community members decide to revitalize their language, it is important to have an accurate understanding of the ages and numbers of fluent speakers who can assist in the revitalization effort.

Absolute Numbers of Speakers

Absolute population size alone is not a definitive indicator of language vitality. Each individual community is embedded in a set of circumstances that affect language use, so that even a small isolated rural community which has little contact with speakers of other languages and in which all members, of all generations, learn and use the local language, cannot reasonably be called endangered. That said, as a general rule, the more speakers, the more likely the community will be able to resist language shift. Put differently, small communities are at greater risk, because they can more easily disappear due to any one of a number of natural or man-made catastrophes. Furthermore, a small community can more easily be assimilated to a large community, and is likely to have fewer resources to resist external pressures. Yet small size alone does not condemn a language to extinction, because the nexus of relevant factors may actually favor language use. A case in point is Icelandic. It is spoken as the first language by a relatively small group of people (approximately 300 000), but it is the national language of the country of Iceland, has a long-standing literary history, and is a language of education. Icelanders have a strong sense of pride in their cultural and linguistic heritage and teach Icelandic to their children as their first language. It is hard to characterize it as being in any way endangered. By the same token, a relatively large speaker community does not guarantee language vitality. Navajo, an Athapascan language spoken in North America, provides an example. Although there are currently approximately 178 000 speakers (2000 census), there is ample evidence of advanced language shift. In 1968, a full 90% of first-grade children spoke Navajo as their first and primary language; by 1990 this figure had dropped to 30%. Despite the relatively large speaker base, it is doubtful that future generations will speak Navajo unless measures are undertaken to assure its continuance.

Proportion of Speakers within the Total Population

The ratio of speakers of the local language with respect to the total population of the local community is an important diagnostic in evaluating language vitality. For safe languages, all of the population speaks the language. In contrast, for extinct languages, none of the population does. In between these two extremes, languages can range from unsafe, with early language shift, where nearly all of the population still uses them, to severely endangered, where only a small percentage do. The larger the percentage speaking and using the language in an active way, on a daily basis, the more likely the language is to maintain its vitality.

In addition to the ratio of speakers of the local language to the number of people who would claim that local language as ancestral, it is useful to

compare how the local language speakers are embedded in a larger social and cultural context. Often local communities are in a minority position with regard to a national culture, represented by speakers of a language of wider communication. The narrower the gap, the stronger the position of the local language.

Trends in Existing Language Domains

A vital language continues to be used in existing domains, while in contrast an endangered language is used in fewer domains. The differences in usage can be placed on a continuum, with safe languages used in all domains for all purposes. Next are situations of what is called diglossia, or the use of different varieties in different contexts. Here a language of wider communication, usually a regional or national language, is the one used in official domains, such as government, education, and other public offices and institutions. The local language, in contrast, is also used in public domains, including not only traditional (local) places of worship or other religious institutions, but elsewhere as well. Typically, the local language is used in the home and informal domains, and the language of wider communication in official domains, and both can be used in public domains. Older members of the community may use only the local language. Next on the continuum is what the UNESCO Ad Hoc Group of Experts terms dwindling domains, when use of the language of wider communication spreads at the expense of the local language. The critical change here is that the local language is used less frequently in the home and is not transmitted to children. This state is further characterized by bilingualism in both the parent and grandparent generations; the children tend to be semispeakers but may be bilingual if the local language is spoken in the home. As this description suggests, at this point there is advanced language shift; the language is endangered and could be ranked as disappearing or even moribund. There are two final stages in this continuum which precede extinction: limited or formal domains is one, and highly limited domains the other. The former is characterized by use of the local language at festivals and ceremonies, in particular when the older generation is present (and therefore using the language). Often the use of the local language is itself tied to the rituals of these occasions and to an extent may be formulaic in usage. UNESCO also includes use of the language in the home in this category when such use is limited to the grandparent generation. The next stage, highly limited domains, represents even greater restriction in use of the local language. It is used only by a very small number of people on very particular occasions, and its use is often ceremonial.

As is clear from this description, the range of domains in which a language is used can be correlated to the generational distribution of speakers and their levels of proficiency. Use in all domains requires fluent speakers of all ages. Loss of intergenerational transmission, by its very definition, is indicative of a restriction in domains, as it signals that the language is not spoken in the home setting with children.

Response to New Domains and Media

Vital, safe languages are not only used in existing domains, but a measure of their strength is the extent to which their use is extended to new domains. These are created as society and conditions change, and an important measure of a language's vitality is the extent to which it evolves with the people who speak it. The general pattern, worldwide, is for the language of wider communication to be used in emerging domains, including formal education and media of all kinds. The question of language use in the media is critical. The media helps spread language use and fosters its growth and/or maintenance. Moreover, use of a language in media is an important indication of that language's prestige and the kind of support it receives from the larger (dominant) culture, the allocation of resources, and so on. Finally, the media represents prestige and affluence, and the language used in the media is associated with both of these.

Education is a key domain for language use. By its very nature, education promotes the language of instruction and fosters its use. Many local languages are not used in schools; in places where they are, they are more likely to be taught as a secondary subject and not used as languages of instruction. For a language to be truly vital, not only must it be taught in the schools, but it also must be used to teach other subjects.

Materials for Language Education and Literacy

Most linguists and local community members agree that education and literacy in the local language are necessary to maintain vitality, or to revitalize a language threatened with endangerment. Some local communities reject this notion, wanting to preserve their oral traditions and to rely solely on them. There is, however, a cost to this decision, as it limits the domains in which the language can be used. Regardless, most regard literacy as essential for local languages. Yet more than half of all languages have no written form, and so a writing system needs to be developed for them in order to use them in education

and literacy programs. Basic pedagogical and reference materials are needed, including textbooks, dictionaries and usable descriptive grammars. Such materials are readily available for languages of wider communication, but not for the majority of local languages. In addition, reading material is needed for literacy as well.

The existence and use of such materials is another diagnostic for assessing language vitality. UNESCO uses a scale of six levels in this assessment; each of these levels correlates with ever-decreasing vitality. At one end, safe and stable languages have an established orthography with a written tradition that includes a full range of written materials; the language is used in official domains such as government and education. At the next level, the materials exist and are used by children in the school, at least in terms of developing local language literacy, but the written language is not used in the government or administration. At the third level, children are exposed to written materials in the schools; they may play a role in education but print media, such as newspapers, journals, magazines, do not use the written form of the language. At the next level, although written materials exist, they are not used in education. Only some community members use them, while for others, their existence may have symbolic value. At the fifth level, the community has knowledge of a writing system and some written materials exist. Finally, at the other end of the community, there is no orthography and the language has no written form.

The singular importance of literacy, as presented by the UNESCO Ad Hoc Group of Experts, is not one which would be embraced by all linguists and by all community activists. It represents a practical view of the role of writing and literacy in the modern world in which local languages compete to survive.

Governmental and Institutional Attitudes and Policies

National and regional governmental policies, laws, and attitudes all play a critical role in the fate of local languages. Policies can be viewed as supportive, fostering the use and development of local languages. They can be benign, not explicitly supportive but also not disadvantageous to local languages. Governmental policies can also be explicitly hostile toward local languages and can actively discourage their use.

There is a direct relation between national-level policies and the attitudes of speakers of the language of wider communication. Positive policies at the national level tend to reflect the overall attitudes of the population toward local languages. One aspect of this is attitudes toward bi- or multilingualism. While some nation-states (such as Canada, Nigeria, or Switzerland) are multilingual, with multiple national and/or official languages, others (such as the United States) are unequivocally monolingual at a national level with regard to language and education policy, as such policies are intended to promote the use of one and only one official language (English, in this case). Because the use of local languages almost always entails at least bilingualism to some degree, so that community members can function at local, regional, and national levels, these languages suffer in countries which are dogmatically monolingual.

National-level attitudes can influence local attitudes. Language is closely associated with the people who speak it; negative attitudes toward a specific language translate into negative thoughts and beliefs about the speakers and their culture, social norms, and heritage. Such negative views can further influence the views community members have of their language. They may perceive it as backward, useless, underdeveloped, and so on, or they may see it as an impediment to advancement in a larger society which does not value their specific local language. Needless to say, such attitudes have an adverse effect on language use and foster language attrition. The role of community members' attitudes toward their own local language cannot be overstated. Where there is a strong sense of pride in the language, it is more likely to be used and less likely to move into an endangerment situation. In cases where language attrition has begun, the chances of reversing language shift are considerably greater if the people have positive attitudes toward the local language. In the absence of these, a revitalization program must begin by fostering community support.

Causes of Language Shift

The precise causes of language shift are specific to each individual endangerment situation, yet several key factors often come into play. These include urbanization, globalization, and what have been called social dislocation and cultural dislocation. Often the causes of language shift center around imbalances in prestige and power between the local language and culture on the one hand, and the language of wider communication and dominant culture(s) on the other. The imbalance, or unequal levels of power, often means that members of the local community are socially disadvantaged in a number of ways with respect to the majority population. In concrete terms, this frequently means that members of the local community are relatively powerless politically, and are less educated and less wealthy, in many cases living in poverty, and with less access to technology and

modern conveniences, than the majority population. One common result is that this socially disadvantaged position becomes associated with, or even equated with, the local language and culture, and so knowledge of the local language is seen as an impediment to social and economic advancement. Socio-economic improvement is thus perceived as tied to knowledge of the language of wider communication, as is renunciation of the local language and culture; for this reason, the situation has been called social dislocation. Social dislocation stemming from lack of prestige and power is one of the most powerful motivating factors in language shift.

Related to social dislocation is what has been called cultural dislocation, which comes about as a result of modernization and globalization. These two related forces bring people from different cultures, speaking different languages, together in a variety of settings, from informal to official, including religious and educational settings. This often results in the culture of the minority giving way to that of the majority. At an extreme, globalization is feared to lead to cultural homogenization. The loss of cultural distinctions supports a loss of linguistic distinctions, since the culture is embedded in the language.

Urbanization is another key cause of language shift and is itself related to cultural and social dislocation. Urbanization brings people from different regions and cultures into the same living and working spaces. They are necessarily required to communicate with one another and so turn to an established lingua franca or language of wider communication. It is not surprising that we find the highest levels of language retention in rural areas; in general, the more isolated a community, the more likely it is to maintain use of the local language. Urbanization has the opposite effect: by bringing people into contact, it facilitates language shift.

Globalization puts even greater pressure on local languages and can be a major factor in language shift. One of the results of globalization is the emergence of at least one global language of wider communication. A global language is a particular type of language of wider communication, and in some instances may supplant the national language in this role. The global nature of trade and commerce has in recent decades put increasing pressure on the need for an international lingua franca, a position currently held by English. Whereas historically it was important for key figures in world politics to be able to communicate, it is now critical that a large number of people in all walks of manufacturing and business communicate with one another, increasing the need for a global language. Some local communities thus see the knowledge of a global language as necessary for socio-economic advancement. In cases where knowledge of a national or regional language is also important, and in fact may be the only language of education, the need to know the global language can supplant the need or desire to know the local language.

Thus in the modern world, multilingualism generally involves knowledge of one or more national languages and, increasingly, of the global language. This represents a change in traditional patterns, when speakers knew a number of local languages. The shift stems from a combination of factors including education, social prestige, and socio-economics. One factor which has led to diminished local-level multilingualism is the current importance of the national language in terms of access to education, higher-paying jobs, the media, and social advancement. The national language provides a language of wider communication which makes knowledge of multiple local languages less necessary. A key characteristic of language endangerment is that use of the local language is limited, not only regionally but also functionally. In some cases, it is used only in the home, while in others, it is used in the village but not for communication with people living outside of the immediate community, and so on. Thus, the uses of the local language have become increasingly limited, with the net result that it is increasingly important for speakers to learn not only a language of wider communication but also, in many instances, a global language.

Strengthening Language Vitality

A number of steps can be taken to strengthen language vitality and reverse language shift. These require action and commitment on the part of community members and at the level of national government alike. Such steps include instituting educational programs which teach and promote use of the local language, and establishing national language policies which make these possible and which support linguistic diversity. An often critical part of such programs is the development of literacy in the local language. In most cases, pedagogical materials need to be developed and teachers need to be trained; in cases of advanced attrition, they will need to be taught the language itself, in addition to language pedagogy.

As this implies, levels of extinction and degrees of fluency (especially among semispeakers) are of great relevance to language revitalization efforts. Disappearing languages often have fluent speakers of many ages who can be enlisted in the work of revitalization. For moribund or nearly extinct languages, this is considerably less likely, and the importance of

semispeakers to the ultimate success of the process grows considerably. An extinct language may still have rememberers who, although they have no active speaking ability, may know individual words or phrases, such as greetings. So even in cases of extinction there may be a variety of levels of lingering knowledge.

England, Nora C.

B Mateo-Toledo, University of Texas at Austin, Austin, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

Nora C. England (Ph.D. 1975, University of Florida) has worked on the description and documentation of Mayan languages for most of her career. She began working on Mayan languages in 1971, specializing in the description of Mam, then the second largest of the Mayan languages of Guatemala. She published a grammar of Mam in 1983 (England, 1983b) and edited a Mam-Spanish bilingual dictionary (Maldonado *et al.*, 1986). The grammar was at that time a model of descriptive grammar writing. She began working on Teko (Tectiteco) (also known as Tektiteko or Tectitico) in 1984 and on Mam dialectology in 1986. In 1988 and subsequent years she has

worked on at least 10 other Mayan languages of Guatemala.

Through her descriptive work she has contributed to a fuller understanding of the grammar of Mayan languages. Some of her contributions have included suggesting an analysis of directionals from a lexical perspective (England, 1983b), arguing for ergative syntactic rules in Mam (1983a), recognizing emphatic constructions other than Topic and Focus in some Mayan languages (1997), describing the syntax of dependent clauses in Mam that require split ergative marking (1983b), and advancing an understanding of Mayan comparative grammar (1989, 1991, 1992a, 2001).

A second aspect of England's work has involved the teaching of linguistics to native speakers of Mayan languages. She began this work in 1971, when she and Will Norman assisted Terrence Kaufman in the training of speakers in basic grammar and dictionary-making procedures at the Proyecto Lingüístico Francisco Marroquín (PLFM), Guatemala. In 1988 and 1989 she initiated two intensive courses in Mayan linguistics through the PLFM, and in 1990 she began to teach linguistics to Maya students in two Guatemalan universities (Universidad Rafael Landívar and Universidad Mariano Gálvez) and founded Oxlajuuj Keej Maya' Ajtz'iib' (OKMA), a Guatemalan institute for linguistic research, staffed by Maya linguists. She has been the advisor to OKMA ever since. In 1997 she provided intensive training in linguistics at OKMA for another group of 45 speakers of Mayan languages, and in 2003 initiated, along with OKMA linguists, a documentation project that involved training eight additional speakers in linguistics. England has been involved with the training of over 100 individuals through PLFM and OKMA, and 50 more in the Guatemalan universities. She currently has two Mayan students in graduate linguistics at the University of Texas. She has participated in the teaching of all of the Guatemalan Maya leaders in the linguistics of their own languages, and her work has provided a model for a productive relationship between Mayan speakers and outside linguists.

Part of her dedication to teaching linguistics to Mayas has led her to publish fairly extensively in Spanish, some of it for teaching purposes and all of it to enrich the literature available in Spanish about Mayan languages (see for example England, 1988, 1992a, 1997, 2000, 2001; England and Elliott, 1990). In addition, she has overseen the publication of more than 20 books written by Maya linguists about their own languages (a dictionary, reference grammars, pedagogical grammars, prescriptive grammars, dialect analyses, and a general book about the Mayan languages of Guatemala).

A third area in which England has worked is on language politics and linguistic identity. This work has depended greatly on her long-term involvement with speakers of Mayan languages and their concerns about language preservation and continuity. Publications in this area include England, 1992b, 1995, 1996, 1998, 2003a, and 2003b.

England was a Professor of Anthropology and Linguistics at the University of Iowa from 1977 until 2001. She was Chair of the Department of Linguistics from 1984 to 1987 and of the Department of Anthropology from 1993 to 1995. She was awarded a MacArthur Fellowship in 1993 and an Iowa Regents Award for Faculty Excellence in 1994. In 2001 she moved to the Department of Linguistics at the University of Texas at Austin as the founding director of the Center for Indigenous Languages of Latin America (CILLA). One of the main goals of the Center is to find ways for speakers of Latin American indigenous languages to study linguistics or linguistic anthropology at the graduate level at the University of Texas. There are currently (2004–2005) six such students at Texas. England's work at the University of Texas is thus directly connected with her interests in teaching linguistics to native speakers of indigenous languages.

Introduction

Despite the enormous range of 'Englishes,' there are few important differences between the principal national standards. The following description deals mainly with the common core. Some notes are also included on salient differences between two loosely defined representative varieties, 'general American' and 'standard southern British English.'

Orthography

Modern English spelling has inherited a mixture of Anglo-Saxon, Norman-French, and classical orthographic conventions, many of which were fixed with the invention of printing in the 15th century. Subsequent phonetic change has been considerable, so that sound–spelling correspondences are now poor. Written English, like French or Irish, is haunted by ghost letters standing for sounds that are no longer pronounced. The 40 or so phonemes of modern English are represented very unsystematically by the 26 letters of the Roman alphabet, singly or in combination. Many phonemes have various possible graphic representations; conversely, many graphemes can represent more than one sound. The situation is particularly chaotic with vowels, where six letters and their groupings serve to encode 17 or more phonemes. As in French, there is a directionality that favors readers over writers: one's chance of guessing how to pronounce a written word is considerably better than one's chance of guessing how to spell a spoken form. It is true that the extent of the orthographic irregularity can be exaggerated – a good deal of English spelling can be shown to be rule-bound. However, the rules are complex, and many of the most common words are highly irregular and have to be learnt by rote.

There are some superficial American–British differences resulting from Noah Webster's reforms in the early 19th century. They include:

- AmE *-or*, BrE *-our* (e.g., *color/colour*).
- AmE *-er*, BrE *-re* (e.g., *center/centre*).
- AmE *-og*, BrE *-ogue* (e.g., *catalog/catalogue*).
- AmE *-ize*, BrE *-ize* or *-ise* (e.g., *realize/realise*).
- Different spellings of some individual words. Examples are (AmE first): *aluminum/aluminium*, *analyze/analyse*, *check/cheque* (on a bank), *defense/defence*, *fulfill/fulfil*, *jewelry/jewellery*, *pajamas/pyjamas*, *skillful/skilful*, *tire/tyre* (on a wheel).

More recent moves for spelling reform have failed for predictable reasons: while the ultimate benefits would be substantial, reform would be extremely expensive and disruptive in the short term; and those who would benefit most – children and others who have yet to achieve literacy – are in no position to influence policy. Opponents of reform argue that a reformed orthography could in any case only encode the pronunciation of one variety of English, and would therefore be less than ideal for others; and that reform would obscure lexical relationships such as *photograph, photographer* or *sign, signature*. Chomsky and Halle (1968) went so far as to claim, indeed, that "Conventional orthography . . . is a near-optimal system for the lexical representation of English words," an assertion that might raise eyebrows in the average schoolroom.

Introduction

Despite the enormous range of 'Englishes,' there are few important differences between the principal national standards. The following description deals mainly with the common core. Some notes are also included on salient differences between two loosely defined representative varieties, 'general American' and 'standard southern British English.'

Orthography

Modern English spelling has inherited a mixture of Anglo-Saxon, Norman-French, and classical orthographic conventions, many of which were fixed with the invention of printing in the 15th century. Subsequent phonetic change has been considerable, so that sound–spelling correspondences are now poor. Written English, like French or Irish, is haunted by ghost letters standing for sounds that are no longer pronounced. The 40 or so phonemes of modern English are represented very unsystematically by the 26 letters of the Roman alphabet, singly or in combination. Many phonemes have various possible graphic representations; conversely, many graphemes can represent more than one sound. The situation is particularly chaotic with vowels, where six letters and their groupings serve to encode 17 or more phonemes. As in French, there is a directionality that favors readers over writers: one's chance of guessing how to pronounce a written word is considerably better than one's chance of guessing how to spell a spoken form. It is true that the extent of the orthographic irregularity can be exaggerated – a good deal of English spelling can be shown to be rule-bound. However, the rules are complex, and many of the most common words are highly irregular and have to be learnt by rote.

There are some superficial American–British differences resulting from Noah Webster's reforms in the early 19th century. They include:

- AmE *-or*, BrE *-our* (e.g., *color/colour*).
- AmE *-er*, BrE *-re* (e.g., *center/centre*).
- AmE *-og*, BrE *-ogue* (e.g., *catalog/catalogue*).
- AmE *-ize*, BrE *-ize* or *-ise* (e.g., *realize/realise*).
- Different spellings of some individual words. Examples are (AmE first): *aluminum/aluminium*, *analyze/analyse*, *check/cheque* (on a bank), *defense/defence*, *fulfill/fulfil*, *jewelry/jewellery*, *pajamas/pyjamas*, *skillful/skilful*, *tire/tyre* (on a wheel).

More recent moves for spelling reform have failed for predictable reasons: while the ultimate benefits would be substantial, reform would be extremely expensive and disruptive in the short term; and those who would benefit most – children and others who have yet to achieve literacy – are in no position to influence policy. Opponents of reform argue that a reformed orthography could in any case only encode the pronunciation of one variety of English, and would therefore be less than ideal for others; and that reform would obscure lexical relationships such as *photograph, photographer* or *sign, signature*. Chomsky and Halle (1968) went so far as to claim, indeed, that "Conventional orthography . . . is a near-optimal system for the lexical representation of English words," an assertion that might raise eyebrows in the average schoolroom.

Table 1 English consonant phonemes

b	v	ð	d	z	ʒ	dʒ	g		r	l	j	w h

Phonology

General

English has a moderately complex phonology: more elaborate than say, Spanish or Japanese, but less so than, for instance, Georgian. There are 24 consonant phonemes (Table 1).

Sixteen of these form voiced/voiceless pairs; though voicing may disappear in word-final position, a fortis/lenis distinction is preserved. Syllable structure permits clusters of up to three consonants (e.g., *strengths* /streŋθs/); clusters of four can occur postvocalically in inflected forms (e.g., *glimpsed* /glɪmpst/). /l/, /m/, and /n/, and (in AmE) /r/ can be syllabic.

The vowel inventory lists anything between 14 and 20 phonemes, depending both on the variety being analyzed and the descriptive approach adopted. Typical listings (for notes see 'American-British Differences' below) are shown in Table 2.

Vowels are generally oral; nasalization can occur, but is not phonemic. Vowel phonemes differ in intrinsic length, but length is not in itself distinctive.

Prominence, or stress, is realized as a combination of pitch, loudness, and lengthening. Word stress is lexically determined and is not generally predictable from the form of a word (compare *'promise*, *pro'mote*; *'photograph*, *pho'tographer*, *photo'graphic*); initial stress is most frequent. Two levels of stress (in addition to unstress) can be usefully identified (e.g., *ˌenter'tainment*). Some words and multiword items have contextually variable stress (compare *this after'noon*, *'afternoon nap*; *they broke 'up*, *she 'broke up the chair*). Stress is phonemic in a few pairs like *'extract/ex'tract*. Unstressed syllables most frequently have a reduced vowel, usually /ə/ (e.g., *malevolent* /məlevələnt/), sometimes /ɪ/ (e.g., *decide* /dɪsaɪd/). Many shorter function words such as articles, auxiliary verbs, prepositions, and pronouns undergo reduction to 'weak' forms with reduced vowels in most contexts: compare *I can* /kən/ *hear you* and *Yes, I can* /kæn/.

The rhythmic features of spoken English that distinguish it from, say, French or Spanish, arise from a combination of syllable structure, word stress, and vowel reduction; the traditional distinction between 'stress-timed' and 'syllable-timed' languages is no longer regarded as valid.

Intonation is multifunctional. Raised pitch contributes to the marking of stress. Tone groups mark off syntactic units such as phrases and clauses, with significant falls/rises at boundaries. Like many languages, English signals incompletion or uncertainty by rising tone movements, and closure or certainty by falling tones. Thus intonation serves not only to distinguish interrogation from assertion, but also to label information as 'given' or 'new' in discourse. Pitch also contributes to the expression of emotional attitudes.

Table 2 American and British vowel phonemes

Keyword	*AmE transcription*	*BrE transcription*
seat	sit	siːt
sit	sɪt	sɪt
set	sɛt	set
sat	sæt	sæt
calm, hard	kam, hard	kɑːm, hɑːd
cot, cough	(kat, kɔf)	kɔt, kɔf
bought, storm	bɔt, stɔrm	bɔːt, stɔːm
book	bʊk	bʊ̈k
too	tu	tuː
up	ʌp	ʌp
turn	(tʌrn)	tɜːn
ago	ə'go	ə'gəʊ̈
day	de	deɪ
my	may	maɪ
now	naw	naʊ
no	no	nəʊ̈
boy	bɔy	bɔɪ
here	(hɪr)	hɪə
there	(ðɛr)	ðeə
tour	(tur)	tʊ̈ə

American–British Differences

While some American and British dialects (e.g., Arkansas and Glasgow) are not mutually comprehensible, speakers of general American and standard southern British English have little difficulty in understanding each other. There are, however, many differences in pronunciation. They include the following:

- BrE has a distinct open back vowel phoneme that is absent in AmE. This is the rounded short /ɔ/ occurring in words like *cot*, *stop*, *on*, *cough*, *often*, *orange*. In AmE these words are pronounced either with /a/ (the same vowel as in *father*, *calm*, *car*) or with /ɔː/ (the same vowel as in *caught*, *storm*, *all*).
- Standard southern British English is nonrhotic: /r/ is only pronounced before a vowel sound. In general American (as in many other British varieties), /r/ is pronounced in final and preconsonantal positions.
- The disappearance of postvocalic /r/ in BrE has generated new diphthongs in some environments (e.g., *dear* /dɪə/, *hair* /heə/).

- The AmE intervocalic tapped allophone of /t/, in words like *writer*, does not occur in BrE.
- The glide vowels exemplified in *day*, *no* differ in quality; they are generally analyzed as monophthongs in American transcriptions (/e/, /o/) and as diphthongs in British transcriptions (/eɪ/, /əʊ/).
- The vowel sounds exemplified in *die, boy*, and *how* are generally analyzed as phoneme sequences in American transcriptions and as diphthongs in British transcriptions.
- Some words written with *a* + consonant (e.g., *fast*, *after*) have /æ/ in AmE and northern British varieties, and /ɑː/ in standard southern British English.
- Some words where /uː/ follows a dental or alveolar in AmE have /juː/ in British English (e.g., *duty*, *tune*, *new*).
- Some words ending in *-ary*, *-ery*, or *-ory* have one more syllable in AmE than in BrE (e.g., *station-(a)ry*).
- French borrowings (e.g. *paté*, *ballet*) tend to have end-stress in AmE and front stress in BrE.

Changes

The last half century has seen much faster changes in pronunciation norms in Britain than in the United States. Up to the 1960s, 'received pronunciation' (RP), a nonregional class-based accent used by a small minority of the British population, had the status of a standard. Its prestige, reinforced by its almost universal use in broadcasting, extended to other English speaking countries such as Australia and New Zealand. RP is now spoken by no more than 3% of the population, and to the extent that an influential pronunciation standard continues to exist in Britain, it is a variety closer to vernacular London speech ('Estuary English'). Vowel quality, in particular, is distinctly different from that of older RP. One consequence of this is that the accent of broadcasters from the 1940s and 1950s sounds decidedly amusing to modern British listeners.

Ongoing changes in pronunciation include the following:

- The use of an unvoiced /ʍ/ or /hw/ in words like *where*, *when* is becoming less common in AmE, and has virtually died out in standard BrE.
- Intrusive /r/ (as in 'Asiar and Africa') is on the increase in BrE.
- The change from /juː/ to /uː/ after dentals and alveolars is continuing, with words like *suit*, *illuminate*, and *enthusiastic* increasingly being pronounced in BrE without /j/, as in AmE.
- Glottalization of medial and final /t/, /p/, and /k/ is growing in BrE.

Lexis

English has an enormous vocabulary – exactly how large is a question to which no clear answer can be given. Well over 600 000 items are included in the *Oxford English Dictionary*, which, however, does not list specialist scientific and technical terminology. In any case, attempts to assess vocabulary size founder on problems of definition. As is becoming increasingly clear from research in phraseology, it is impossible to draw a principled line between orthographic words and other fixed lexical items: compare *cosmetic*, *make-up* (n), and *make up* (v), or *unemployed* and *out of work*.

The different sources of the English word stock are reflected both grammatically and stylistically in the modern language. According to studies cited by Algeo (1998), only 5.4% of the words listed in a dictionary originate from Old English, but these account for 74.5% of the words in newspaper running text. They include most of the highest-frequency vocabulary, and almost all function words such as determiners, auxiliaries, and prepositions. Most other older English words came into the language either from Norman French, or from Latin and Greek during the Renaissance. Besides providing English with much of its learned vocabulary, these later lexical injections have allowed the language to develop a wealth of variant forms for everyday concepts. Speakers and writers can frequently choose between down-to-earth forms (usually, though not always, the older words) and more formal or elevated alternatives (usually the later imports): for example *buy* or *purchase*; *try*, *attempt*, or *endeavor*; *start*, *begin*, or *commence*; *answer*, *reply*, or *respond*; *tell* or *inform*; *get off* or *alight*. For more literary purposes, the possibilities can be almost daunting. Words describing the reflection and transmission of light, for instance, include *shine*, *glitter*, *glisten*, *gleam*, *glow*, *sparkle*, *twinkle*, *glimmer*, *blaze*, and *coruscate*.

The paucity of inflections makes the language morphologically hospitable, and English continues to borrow freely from elsewhere. Algeo (1998) lists 20th-century borrowings from 56 languages, with by far the highest proportion coming from French. Most new English words, however, are home-grown, created either by shifting word class with no formal change (most high-frequency nouns have verbal homonyms, and vice versa), by compounding (e.g., *computer-literate*), or by affixation (e.g., *pro-life*). Over the last century, the latter process has been the major source of new vocabulary. Although English has few inflections, it has a good deal of derivational morphology, with well over 100 affixes in common use, many of them productive. These serve to modify

the meanings of words (e.g., *un-*, *counter-*, *re-*, *-ess*, *-hood*, *-ism*, *-ship*), and/or (especially in the case of suffixes) to change their word class (e.g., *en-*, *pro-*, *-age*, *-ance*, *-ful*, *-ly*, *-en*, *-ify*, *-ize*). Among the range of affixes there is a stock of naturalized morphological formative elements, originally borrowed mainly from Greek and Latin, which are particularly productive in present-day word-formation: for example, *auto-*, *eco-*, *cyber-*, *mono-*, *macro-*, *inter-*, *-ology*, *-cratic*, *-phile*, *-phobe*.

While the vast bulk of English vocabulary is common to AmE and BrE, there are a fair number of well-known differences. Many words in common use differ in their reference (e.g., *truck*, *mad*, *pavement*, *chip*); very frequently, different words are used for the same concept (e.g., *elevator/lift*, *faucet/tap*, *check/bill*). The independent development of industry in the two countries is strikingly reflected in, for instance, vocabulary relating to cars (*hood/bonnet*, *trunk/boot*, *fender/wing*, *gas pedal/accelerator*, *windshield/windscreen*, *gear shift/gear lever*).

Morphology and Syntax

General Characteristics

In traditional typological terms, modern English is situated toward the 'isolating' end of the spectrum. Little of the older inflectional morphology remains; what there is is largely redundant. Nine or so major word classes are commonly distinguished. Grammatical relationships are expressed primarily through word order (SVO) and the use of function words, particularly prepositions and auxiliary verbs. Case structure is nominative-accusative. Topic is not generally distinguished grammatically from subject. Word, phrase, and clause are relatively distinct categories, but there is considerable scope for phrasal and clausal embedding, exploited especially in the formal written language. Constituent order within phrases is mixed, with modifiers generally preceding heads and complements following.

Word Classes

- **Count and mass nouns** are distinguished syntactically; count nouns have an inflected plural form. Formally singular nouns referring to human groups may have partial plural agreement, especially in British English. An inflectional/clitic genitive exists, used preferentially with nouns that have human reference. English differs from most IE languages in having no grammatical gender.
- **Determiners** include a range of quantifiers, demonstratives expressing a two-term distal contrast, and a distributionally and semantically complex article system, similar in most respects to its counterparts in other Western European languages, but using zero article for generic reference (compare German *die Musik*, Italian *la musica*, French *la musique*, English *music*). There is some overlap between determiners and pronouns.
- **Adjectives**, as in most IE languages, form a large and semantically heterogeneous class. Most can function both attributively and predicatively; a few are limited to one or other position. There are semantically based ordering constraints. Comparison is inflectional (with shorter adjectives) or analytic. There is some overlap between the adjective and adverb classes.
- **Pronouns** are personal, reflexive/emphatic, reciprocal, relative, indefinite, possessive, demonstrative, and interrogative. Personal pronouns (first and third person) have distinct case forms; third-person singular forms encode natural gender. Relative and interrogative pronouns distinguish human from other referents (*who/which*; *who?/what?*), and retain a moribund case distinction (*who/whom*).
- **Lexical verbs** have a multifunctional base form that serves as a present tense (except in the third person singular), as an imperative, and as an infinitive (usually marked by a particle *to*). There is an inflected third-person singular present, and an inflected past tense. Morphologically marked nonfinites are a present participle or gerund, and a 'past participle' identical in regular verbs with the past tense. Irregular verbs form their past tenses and past participles in various ways, mostly involving a vowel change. Participles can combine verbal with adjectival or nominal functions.
- **Primary auxiliaries** are grammaticalized versions of *be* (used to construct passive and progressive verb forms), *have* (used in perfective verb forms), and *do* (used in some interrogative and negative structures).
- **Modal auxiliaries** (*will*, *shall*, *would*, *should*, *may*, *might*, *can*, *could*, *must*, and *ought*) and quasi-modals (e.g., *had better*) express varying degrees and nuances of epistemic, deontic, and dynamic modality, with a good deal of semantic overlap. Modals are invariable, lacking nonfinite and past forms.
- **Adverbs** are a heterogeneous class, including both clausal modifiers and items that modify particular clause elements. Adverb particles such as *back*, *away*, *on*, *off*, *in*, *out*, *over*, up form an important group, overlapping considerably with the preposition class; they combine extensively with verbs to form phrasal verbs.

- **Prepositions and conjunctions** constitute limited but not completely closed overlapping classes, with a growing number of multiword members.
- **Inserts** such as *Hi*, *Yeah*, *OK*, *Sorry*, *Look*, *Please*, *Damn!* form a distinct word class in conversational speech.

Noun Phrase Structure

Nouns can be premodified by determiners, adjectives, and noun modifiers, in that order. Complex hierarchical structuring is possible, facilitated by the freedom with which nouns can act as modifiers; this contributes to the dense and economical approach to information packaging found in some written registers. Some determiners show number agreement; premodifying nouns are generally unmarked for number.

Relative clauses postmodify, as do nonfinite clausal modifiers. Relativized NPs can function as subjects, direct or oblique objects, or possessives in relative clauses. Restrictive relative clauses have a hybrid character: they can be integrated into a preceding noun phrase by simple juxtaposition, by a relativizer (*that*), or by a relative pronoun (*who, whom, which*), which functions as an argument in the relative clause. The choice is subject to complex syntactic and stylistic constraints.

The Verb Group: Tense, Aspect, Modality, Mood, and Voice

English has a relatively rich and complex verbal system, especially in main clause use. The small inventory of morphological distinctions is supplemented by a range of periphrastic forms constructed with primary and modal auxiliaries. Tense, progressive and perfective aspect, mood, and voice can all be expressed separately or in combination though the verb group. Some key features:

- English perfective aspect encodes anteriority, often with continuing relevance.
  We couldn't get in because I had lost my key.
  I'm afraid Jane has had an accident.
- Future events arising out of present situations are generally referred to by present forms (especially the present progressive or *be going* + infinitive). Reference to future events viewed as detached from the present uses a bleached modal auxiliary *will*.
  We're meeting again tomorrow.
  Look out – we're going to crash!
  You will be paid at the end of the month.
- 'Irrealis' modality is expressed principally by the use of modal auxiliaries or, especially in subclauses, by past tenses; also (mainly in AmE) by subjunctives.
  It would be better if you came tomorrow.
  She must have forgotten.
  It's important that she be told. (AmE)
  It's important that she should be told. (BrE)
- English is unusual in that oblique arguments can act as subjects of passive verbs.
  I've been given one of those forms.
  She hates being shouted at.
- Reflexive and middle relations can be indicated by pronouns (e.g., *hurt oneself*), but are often unmarked (e.g., *shave*, *marry*).

Clause and Sentence Structure

Canonical SVO order is generally observed in written English; in informal speech, departures from the norm such as fronting and left-dislocation are more common. Nonprepositional indirect objects precede direct objects. Verb and object constitute a tight unit, not usually separated; otherwise, adverbial elements occupy a variety of positions. Relative and interrogative pronouns and adverbs are initial in clauses. Preposition-stranding is common. Interrogatives are formed by inversion of the subject and operator (the first of any primary or modal auxiliaries), negation by adding *not* to the operator. (Multiple negation is common in nonstandard dialects.) In the absence of an auxiliary, *do* is used as a dummy operator.

Nominative and accusative case are marked positionally, with redundant morphological marking in some pronouns. There is vestigial subject-verb number agreement in the present tense of lexical verbs and primary auxiliaries. Pronoun dropping is ungrammatical except in imperatives and certain elliptical structures.

Verbs have a wide range of possible complementation patterns; subcategorization rules of individual verbs are only partly predictable on semantic grounds.

Coordination and subordination operate as in most IE languages. Various types of subordinate clause with differing structural features can have nominal, adjectival, or adverbial functions in matrix clauses. Verbal structures in most subordinate clause types exhibit a more reduced range of tense/aspect expression than in main clauses. Embedding can in general be recursive up to the limits of processability. There are complex constraints on extraction from embedded clauses in interrogative and relative structures.

The sentence, as a unit, is essentially a feature of the written language. Conversational speech is not easily analyzed into sentences, and is perhaps better seen as constructed of 'clausal' and 'nonclausal' units (Biber *et al.*, 1999), which may be loosely linked into utterances in an add-on fashion rather than being organized into structural hierarchies.

Information Structure

English follows the quasi-universal tendency to put 'given' or background information before new. Formal written English has few topicalization devices; in order for given information to come first in an utterance without disrupting canonical word order, it therefore tends to be encoded as subject. The merging of topic and subject is facilitated in several ways. English allows an unusually wide variety of participant roles to be encoded as active subjects, including (depending on the verb) agent, patient, experiencer, benefactive, instrument, temporal, and locative. Indirect and prepositional objects can become passive subjects. The '*have*-passive' enables experiencer to be encoded as subject (e.g., *She had her roof blown off in a storm*). English is also rich in lexical alternatives with different argument selections (e.g., *admire/impress*, *frighten/fear*, *notice/strike*). In conversational speech, given-new relations are also indicated by fronting, left-dislocation, or phonological prominence.

Changes

Older changes that are still working their way through the language, and some newer developments, include:

- continuing spread of the *going-to* future
- increased use of the progressive with stative verbs (e.g., *I'm understanding German better now*)
- replacement of *shall* by *will*, and of *should* by *would* in some contexts
- spread of the *get*-passive
- decline in the use of the subjunctive, especially in BrE
- general reduction in the use of modals (see Leech, 2003)
- increased use of phrasal verbs
- spread of conditional structures with parallel verb forms in speech (e.g., *If you'd have asked me I'd have told you.*)
- increased use of noun + noun compounds
- disappearance of *whom*
- increased use and acceptability of noncanonical pronoun case in conjoined subjects and objects (e.g., *John and me went* . . . ; *between you and I*)
- grammaticalization of *you guys/folks* as new second-person plural pronoun
- increased use of singular indefinite *they*, partly as alternative to nonsexist *he or she*
- replacement of possessive determiner by object pronoun before *-ing* form (e.g., *This led to them being arrested.*)
- spread of analytic comparatives and superlatives (e.g., *commoner* > *more common*)
- dropping of complementizer/relative *that*
- increased use of preposition stranding.

For an excellent detailed discussion of ongoing syntactic changes, and further references, see Denison (1998).

American–British Differences

The grammatical systems of standard AmE and BrE are virtually identical. Minor differences, some of which are disappearing with the growing influence of AmE on BrE, include those exemplified below:

AmE	BrE
He just went home.	*He's just gone home.*
Do you have a problem?	*Have you (got) a problem?*
I've never really gotten to know her.	*I've never really got to know her.*
It's important that he be told.	*It's important that he should be told.*
Yes, I may.	*Yes, I may (do).*
The committee meets tomorrow.	*The committee meet/meets tomorrow.*
He probably has arrived by now.	*He has probably arrived by now.*
It looks like it's going to rain. (informal)	*It looks as if it's going to rain.*
He looked at me real strange. (informal)	*He looked at me really strangely.*

Standardization and Prescriptivism

Standardization continues in the English-speaking world, with regional dialects converging on standard varieties, and American English exercising increasing influence on usage in other countries. At the same time, however, increased democratization is reducing the social prestige of the standards, and there is somewhat more tolerance of variation, at least in speech, than, say, 50 years ago. The written–spoken divide is narrowing: with the continued growth of the spoken media, speech is no longer regarded as a poor relation of writing, and characteristically spoken lexical and grammatical elements are making their way into the standard written language. The recent explosion in electronic written correspondence has further reduced the gap, widening the use of relatively informal written registers at the expense of more traditional styles.

However, prescriptive attitudes to usage remain entrenched and powerful in both the United States and Britain. A command of the orthographic, grammatical, and rhetorical conventions of the standard written language is commonly equated with superior intelligence and educational achievement; failure to master these conventions can constitute a serious

obstacle to educational or professional advancement. 'Standard' is typically seen as being synonymous with 'correct,' and 'nonstandard' with 'incorrect'; regional or ethnic dialects such as cockney or Afro-American Vernacular English are widely believed to be grammatically deviant and ill-structured.

English is often perceived as being in a state of decay: threatened by variable and changing usage, the encroachment of nonstandard forms, a growing lack of respect for time-honored rules, and the failure of schools to provide adequate grammar teaching. Linguistic and moral decline may be seen as going hand in hand. The British politician Norman Tebbitt, echoing voices from the 18th and 19th centuries, famously declared in 1985 that "If you allow standards to slip to the stage where good English is no better than bad English, where people turn up filthy ... at school ... all those things tend to cause people to have no standards at all, and once you lose standards then there's no imperative to stay out of crime."

The feeling that the language is in danger generates a belief that grammarians, lexicographers, publishing houses, the media, and the educated community have a duty to defend it. In both the United States and Britain, radio and TV stations, magazines, and newspapers receive voluminous correspondence complaining about the 'mistakes' of journalists, broadcasters, and public figures (and, in Britain, condemnation of their 'Americanisms'). Many newspapers and magazines publish regular columns by language gurus on questions of usage. Prescriptive usage guides find a ready market among those who wish to see their prejudices reinforced or who have been made to feel insecure about their command of their own language. (A recurrent advertisement in the British press begins 'Shamed by your mistakes in English?') Such guides often continue to reproduce the 18th- and 19th-century proscriptions against preposition-stranding and split infinitives. Other current targets include novel part-of-speech shifts (e.g., *to task*, *to showcase*); the use of plural concord with group nouns (e.g., *the team are*, standard in BrE, but often condemned for being 'illogical'); 'misplaced' *only*; dangling participles; changes in the meanings of words (e.g., *anticipate*, *disinterested*, *enormity*) and in their grammatical scope (e.g., the use of *hopefully* and *thankfully* as disjuncts); singular indefinite *they* (centuries old); *less* before a plural noun (used by King Alfred); 'misuse' of *me* and *I* in conjoined subjects and objects (there are examples in Jane Austen and Shakespeare); and – perhaps most inflammatory of all – the illegitimate use or omission of the possessive apostrophe. (As Steven Pinker points out [1994], prescriptive rules are often so psychologically unnatural that only those with access to the right schooling can manage to abide by them; so they serve as shibboleths, differentiating the elite from the rabble.)

Despite the growing tolerance of regional pronunciation, elitist attitudes persist: a letter to the *Sunday Times* in March 1993 described speakers of 'Estuary English' as resembling "the dregs of humanity." Particular regionalisms are still widely proscribed or made fun of. British *h*-dropping in words like *horse*, *hurry*, *home*, common in Eastern England, is typically condemned as lazy, slovenly, or slipshod, generally by nonrhotic speakers who do not see their own *r*-dropping at all in the same light.

There have been quite strong counter-currents to prescriptive attitudes in educational and other circles at various times over the last century, but more liberal and relativistic views of linguistic authority and correctness have tended to meet considerable opposition. Finegan (2001) gives an interesting account of the outrage with which the publication of Webster's 'permissive' *Third New International Dictionary* was greeted in 1961. Jean Aitchison, a British linguist who gave the BBC Reith lecture series in 1996, received copious hate mail for questioning popular views of correctness.

The Future

As English increasingly takes on the role of a world lingua franca, it is certain to develop in interesting ways. One can imagine that a future international variety of English (or group of international varieties) might detach itself somewhat from the American–British standards; alternatively, it might pull them along with it. In either event, narrowly prescriptive attitudes of the kind described above are likely to appear increasingly parochial. While we have no way of knowing how an international English might evolve, we can speculate that it might simplify, regularize or dispense with some of the features that make the present-day language hard for non-native speakers to learn and use. Such changes might include the reduction of consonant clusters; the regularization of word stress and speech rhythm; the simplification of verb phrase grammar, perhaps accompanied by an increase in the range of grammatical particles; the reduction of the modal verb inventory; the regularization of verb complementation structures; and the disappearance of indefinite and perhaps definite articles. International English might also provide a more favorable environment for spelling reform.

English Spelling: Rationale

J Mountford, University of Southampton, Southampton, UK

© 2006 Elsevier Ltd. All rights reserved.

The Standard Orthography of English (SOE) is the most widely used writing system in the world, and an enormous educational effort goes into teaching it and, of course, learning it. Linguistics has not so far made the massive contribution to the efficacy of this effort that might have been expected: the study of graphology has lagged behind that of phonology, grammar, semantics, and other aspects of language, and applied linguistics has been more concerned with new orthographies than with old ones.

Writing System, Spelling, Orthography

The term 'writing system' has been used variously by linguists and has not always been distinguished from 'spelling system,' although it is clear that a writing system like SOE has components that lie outside the spelling system – most obviously, punctuation. In addition, there are writing systems that are not at all like SOE. Pitman's shorthand, for instance (or Gregg shorthand), looks quite different, and is quite different in its spelling system (e.g., no digraphs, homophones not distinguished) as well as in its script (the written shapes and the spatial disposition of its graphemes). This example points to another aspect of writing systems: namely, that there is more than one functional kind of writing system. Pitman's shorthand is a stenography, a special-purpose writing system. SOE, by contrast, is a general-purpose writing system, a class of writing system for which 'orthography' is an appropriate name.

The Basis of a Shared Rationale

Two Prongs of Spelling Analysis

A rationale of English spelling should enable teachers, learners, and people in the community (parents, for example) to give a rationale for the spelling of particular words – a 'spelling analysis'; yet good spellers, including good teachers, are rarely able to help weak spellers in this way.

The structure of the spelling system indicates two lines of attack – two prongs. Both of them derive from the grammar, or 'lexicogrammar,' of the standard form of the language – the first directly (see the section "Graphomorphemics") and the second (see the section "Graphophonemics") indirectly via the phonology (selecting a 'reference pronunciation' appropriate to the language community). Common to both is the mathematical concept of the one-member set, familiar already in the analysis of linguistic structure: in a scale, or rank-scale, of units, each unit (except the lowest) consists of one or more members of the next unit below. Take words and syllables: every word consists of 'one or more' syllables, and in English, words of one syllable, such as *aim* or *guess* are particularly common and are known as 'monosyllables.' This is a familiar example of 'one or more' constituency – though, as

nominative, and identified the subject wherever it was positioned, and the accusative form *þone cyning* signaled the object. Already in Old English, however, the order Subject-Object (as in the first of our examples) was much more frequent than Object-Subject. This order was the usual one even when case marking would have made the grammatical relations clear without the help of word order.

The position of the verb was also variable. Old English exhibits the preference for verb-second order in main clauses and verb-final order in subordinate clauses found in the other early Germanic dialects, but in Old English, verb-second position in main clauses was not as regular as it is in, for example, Modern Dutch, and only about 50% of subordinate clauses have verb-final order. Order within the noun phrase was also variable but far from free, with the prenominal order Determiner Adjective Noun familiar from Modern English already the unmarked pattern. The postnominal order found in *men þa leofestan* 'most beloved people' (lit. 'people the belovedest') was mostly limited to vocatives and poetry, and is presumably a relic of more widespread postnominal positioning of modifiers in Germanic. The scene was set for further dependence on word order in the Middle English period.

English Lexicography

P Hanks, Brandeis University, Waltham, MA, USA and Berlin-Brandenburg Academy of Sciences, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Bilingual Beginnings

From earliest times, students have noted translations above words in foreign-language texts. Murray (1900) traces the origins of English lexicography to these notes, called 'interlinear glosses,' which are found in many Latin documents that survive from the Old English period. In some monasteries, interlinear glosses were collected into a document called a 'glossarium.' Such early glossaries originally listed the words in the order in which they were read in texts, but "as these manuscript lists came to be copied and re-copied, it was seen that their usefulness would be increased by putting the words and phrases into alphabetical order" (Murray, 1900). The development of these lists into more sophisticated language tools was given a great boost by the invention of printing, which enabled elaborate alphabetical lists of words, with explanations, to be reproduced in hundreds of copies. Lexicography has always been closely associated with printing and publishing. Johannes Gutenberg invented the printing press in Mainz, in about 1450, and by 1474, the new invention had been brought to England by William Caxton. In the century that followed, bilingual and multilingual compilations of technical terms in various domains, often with discursive and even anecdotal comments by the compiler, began to flourish. An example may be given from William Turner's *The Nature of herbes in Greke, Latin, Englishe, Duche & Frenche wyth the commune names that Herbaries and Apotecaries use*, published in 1548:

> **Anthenus.** *Anthenus* siue *Chamaemelon* is called in englishe *Cammomyle*, in duch *camillen*, in frenche *camomille*. Camomilla is deuided into three kyndes, the firste

kynde is called *leucanthemon* because it hath a whyte floure and of the commune herbaries Camomilla romana, and in englishe cammomyle, thys herbe groweth on Rychmund grene, and in Handsley heth in great plentie. The second is called in greke *chrysanthemon* because it hath a golden floure. I founde it once in a corne fielde betwene Basyle and Surike, and haue neuer sene it any where els in all my lyfe, it maye be called in englishe *yea lowe camomyle*. The thirde kynde is named in greeke *Eranthemon* because it groweth in the sprynge of the yere. I haue sene it in Englande but very rare, some call it *amariseam rubeam,* and they call it in Englishe *red mathes*, alij, *red mayde wed*, alij, *purple camomyle*. Camomyle is hote and drye in the fyrste degree.

Early dictionaries played a vital part in bringing the new learning and culture of the European Renaissance to England. As the cultural importance of vernacular languages grew, bilingual works were compiled, explaining the meaning of words in French, Italian, and Spanish literature for a sophisticated English-speaking audience and for travelers. Browsing these Tudor dictionaries (using Lancashire's (1999) *Early modern English dictionaries database, EMEDD*) gives a fascinating insight into the Renaissance mind set, and also the extent of Renaissance linguistic sophistication. French was the language of diplomacy as well as culture in Renaissance Europe, so it is not surprising that the earliest true dictionary published in England, in 1530, was *Lesclarcissement de la langue francoyse*, by John Palsgrave, tutor to Princess Mary (later Queen Mary I). This ambitious work contains 18 890 entries, together with a French grammar, being the first in a long tradition of dictionaries with supplements, bringing added value to the basic word list. As shown in *EMEDD*, it contains both simple glosses (example (1)) and guidance on phraseology (example (2)):

(1) **Alegyaunce,** uasselaige *s ma*.
Alley (to walke in), alee *s fe*.
Alfyn (a man of ye chesse borde), avlfin *s ma*.
Alyaunce, aliance *s fe*.
Alyen (straunger), alien *s ma*.
Alye or **alyaunce,** aliance *s fe*.
Alysandre (an herbe), alisandre *s fe*.
Alle (an instrument for souters), alaisne *s fe*.
Alsoulne day, le iovr des mors *ma*.
All maner wylde foule, uolaille *s fe*.
Alhalowentyde, la tous sainctz *fe*.
Alledgynge (of a matter), allegation *s fe*.
Almaygne (a man), alement *s ma*.
Almaygne (a countre), alemaigne *s fe*.
Almery (to put meate in), unes almoires *fe*.
Almysdede, avlmosne *s fe*.

(2) **Astore** . . . *This house is astored of all thinges plentuously:* Ceste mayson est foysonnée de toutes choses.
Brede . . . *I brede as many pygges aboute my house as two of my neyghbours:* Je nourrys *or* je eslieue autant de coychons autour de ma mayson come deux de mes voysyns.
Butt . . . *This house butteth vpon ye lordes landes:* Ceste mayson marche sur les terres du seignieur, *or* confine, *or* confronte.
Contayne . . . *This house is scarsely able to contayne his plate:* A payne peult ceste mayson contenir sa vaisselle.
Convaye . . . *Conuaye this man to my house tyll I come:* Menes cest homme a ma mayson tant que je viengne.

The most important of the early Latin–English dictionaries was Thomas Thomas's *Dictionarium linguae Latinae et Anglicanae* (1587), containing over 36 000 entries. It has a fairly sophisticated lexicographical apparatus, showing part-of-speech class, inflections, and derivation. Occasionally, brief references to authors are given, e.g., 'Plin.' for Pliny. Glosses are in both Latin and English. It was the standard work used by pupils and teachers in the newly founded 'grammar schools,' which taught Latin grammar (not English grammar), and 'public schools,' which are (or rather became) private schools. The following entries show how Thomas's *Dictionarium* was arranged (taken from *EMEDD*):

Alienatio, -onis, f.g. verb. Ab *alieno*. Alienation or altering, withdrawing of the minde from the friendship of anie man: deliuerance of possession of another. & **alienatio mentis,** Plin. The losse of ones witte: when one is bestraught.
Alienatus, -a, -um, part. p.b. Alienated, put awrie: altered: estranged, angrie: & **alienatus mente,** [Plin.] Troubled in his minde, out of his witte.
Alieno, -as, p.b. Plin. To alienate: estrange: to put awaie: to aliene or alter possession.
Alima, Medicines which either asswage hunger, or keepe a man from it.
Alimentum, -ti, n. g. verb. ab *alo*. L p.b. Sustinance, foode, nourishment, liuing.
Alioqui, siue **alioquin**, coniunctio, p.b. Otherwise: else: except that: if not.
Alipaenea, Caels. Medecines made without fatte.
Alipastos, Flesh that hath no fat.
Alipes, -edis, ex *ala* & *pes*, p. l. Ouid. Swift of foote.
Alipterium, p.b. Cael. A place in bathe or sloufs, where men were annointed.
Aliptes, -ae, m. g. p.b. The Master of the wrestlers, which with oyle did annoint them that should wrestle naked. Also a Chirurgion, which with oyle, & fatte mollifying emplasters laide to the outward parts, doth heale woundes and outward diseases.

In 1598 and 1599 respectively appeared the first major Italian–English dictionary and the first Spanish–English dictionary. John Florio's *A worlde of wordes* (1598; second edition, 1611, retitled *Queen*

Anna's new world of words), an Italian–English dictionary, offered translations of much contemporary vocabulary and even some slang. It contains over 50 000 translations. Florio was born in London in about 1553, the son of an Italian Protestant refugee. He studied at Oxford, and in 1604 he obtained a position at court. In addition to compiling a dictionary, he also published a very successful translation of the essays of Montaigne. The following entries are examples from Florio's dictionary, taken from *EMEDD*:

Alice, a little fish called a pilcher or a sprat, like a herring.
Alicorno, an vnicorne. Also an vnicornes horne.
Alida, alida carne, stale, tainted, mortified or flie-bitten meate.
Alidare, to mortifie, taint or make meate stale.
Alie, vsed for Ale: wings.
Alienare, to alienate or estrange.
Alienatione, an alienation or estranging.
Alieno, an alien, a stranger, a forraine, a frenne.
Alieta, a kinde of eagle which alone fixeth hir eies against the sunne.
Aliga, as Alga.
Aligare, to tie or binde togither.
Aligero, one bearing wings.
Alima, an herbe whereof eating a little one shall bee kept a long time from hunger.
Alimentore, to nourish, to feede, to sustaine.
Alimento, nourishment, sustenaunce, foode.
Alimo, a kinde of tree in India. Some take it for Licorice.
Aliossi, a play called Nine pins or keeles, or skailes.
Alipo, a weede growing vpon rocks by the sea side.
Aliso, a blew lillie flower.
Alisma, a kinde of weede growing in fens or marshes.

English political relations with Spain were troubled during the 16th and early 17th centuries, not only because the Spanish were among those attempting to reclaim Protestant England for the Roman Catholic Church, but also because of naval rivalry on the high seas, English military intervention in the Spanish Netherlands, and other points of tension. John Minsheu's *Dictionarie in Spanish and English* (1599), at least in part, was not only a work for literary scholars, travelers, and merchants, but also served a purpose similar to that of Russian–English dictionaries in America during the Cold War, namely, aiding understanding the language of the enemy.

The First Monolingual English Dictionaries

In Tudor times, pedagogical works were published vigorously, defending and promoting the use of English as a literary language. One of the best examples was the *Elementarie* (1582) by Richard Mulcaster, headmaster of Merchant Taylors' School, who stated, "I take this present period of our English tung to be the verie height thereof, bycause I find it so excellentlie well fined both for the bodie of the tung it self, and for the customarie writing thereof." He went on to propose, "It were a thing verie praiseworthie in my opinion, and no less profitable then praise worthie, if som one well learned and as laborious a man, wold gather all the words which we use in our English tung, whether naturall or incorporate, out of all professions, as well learned as not, into one dictionary." It would take 150 years for Mulcaster's dream of a dictionary listing all English words to be even approximately fulfilled.

The title of the earliest monolingual English dictionary, Robert Cawdrey's *Table alphabeticall … of hard usual English words, … gathered for the benefit & helpe of ladies, gentlewomen, or any other unskilfull persons* (1604), gives a clue to the motivation of its compiler, a motivation that was not very different from that of the compilers of bilingual dictionaries of the same period. Cawdrey's main sources were Thomas Thomas's Latin *Dictionarium* of 1587, mentioned previously, and a teaching manual of 1596 called *The English school-maister,* by Edmund Coote, which included a list of English 'hard words.' Cawdrey's purpose was to explain unfamiliar words, not to compile an inventory of all the words. This was particularly necessary at the start of the 17th century for two reasons. In the first place, a vast number of words of Latin origin had been introduced into English in the preceding century. These were known as 'inkhorn terms,' because they were associated mainly with learned writing, rather than with use in the vernacular speech of ordinary English people. At times, it seemed almost as if writers were vying with one another to introduce Latinate words into English, with results that did not contribute to conspicuous comprehensibility. Second, although a large number of English 'grammar schools' (teaching Latin grammar) were founded in the mid-16th century, these were open only to boys. Many aristocratic families engaged Latin tutors for their sons, but rarely for their daughters. This explains Cawdrey's reference to ladies and gentlewomen in the same clause as "other unskilfull persons." As a result, in some places women were probably unable to understand the words of their own language, as it was preached to them from the pulpit and used in other learned and official contexts. This continued to be reflected in the subtitles of English dictionaries throughout the 17th century, including the dictionaries of Cockeram ("for ladies and gentle women, …

clarkes, merchants, young schollers, strangers, travellers, and all such as desire to know the plenty of English") and Blount ("[for] the more-knowing women and the less-knowing men"). The following list is an example of entries from Cawdrey's 1604 dictionary (taken from *EMEDD*; see Lancashire, 1999):

alchimie, the art of turning other mettals into gold
alien, a stranger
alienate, to estrange, or with-drawe the mind, or to make a thing another mans
allegorie, similitude, a misticall speech, more then the bare letter
allegiance, obedience of a subiect
allusion, meaning and pointing to another matter then is spoken in words
allude, to speake one thing that hath resemblence and respect to another
altercation, debate, wrangling, or contention
altitude, height
amaritude, bitternesse
ambage, long circumstance of words

Cawdrey's little book, containing about 2500 entries, not only proved popular but also inspired numerous imitators and improvers, beginning the long accretive tradition of English lexicography, in which each new dictionary builds on the foundations laid by its predecessors. John Bullokar's *English expositor* (1616) doubled the size of Cawdrey's entry list to about 5000 entries and expanded some of the definitions, without much attention to method or principle. In particular, Bullokar introduced discursive comments on herbs and beasts. This was followed in 1623 by Henry Cockeram's *The English dictionarie: an interpreter of hard English words*. Cockeram was sensitive to distinctions of style and register and divided the vocabulary of English into two sections: "the choicest words now in use" and "the vulgar words." There is also a third section, an encyclopedic guide to mythological figures and literary allusions.

In 1656 appeared the *Glossographia* of Thomas Blount. Blount was a lawyer and, not surprisingly, the *Glossographia* includes many legal terms, as well as other technical words. It contains approximately 11 000 entries and was the first English dictionary to attempt to explain the etymologies of English words. Another important 17th-century contribution to English lexicography is *An English dictionary* by Elisha Coles (1676), which included cant words and dialect words as well as hard words.

In 1658, Edward Phillips published *The new world of English words*. This work borrowed heavily from Blount, though commenting disparagingly on him in the 'advertisement' at the front of the book. Blount hit back with a pamphlet entitled *A world of errors discovered in the new world of words*, in which he showed that Phillips had not only made errors of his own, but had even copied errors from the *Glossographia*. The effect of this spat seems to have been to improve sales, possibly of both books, but certainly of Phillips's, which continued in print, with occasional new editions, until the end of the century. In 1706, Phillips's work was revised and doubled in size (38 000 entries in a folio volume) by John Kersey, who in 1708 published an improved and abridged version (35 000 entries) in handy octavo format under the title *Dictionarium Anglo-Britannicum*. Kersey had already ventured into lexicography in 1702, with *A new English dictionary* – a list of 28 000 common words that had not previously been included in English dictionaries. In this work, the place of a definition is often taken by an example of use or context, thus:

Ake, as, my head akes
An ***Apron***, for a woman

Although it is by the same author, the *Dictionarium Anglo-Britannicum* is very different. There could be no better example of the fact that lexicography is accretive. Phillips improved Blount's definitions, and Kersey improved Phillips's before going on to improve his own work. He added technical terms from sources such as Harris's *Lexicon technicum* (1704) and rare words from Ray's *Collection of English words not generally used* (first published in 1674). Kersey's lexicography is remarkable for its clear, concise definitions and for the systematic identification of the source languages of words.

The 18th Century: Bailey, Martin, and Johnson

The most important English lexicographer before Johnson is Nathaniel Bailey, a schoolmaster whose *Universal etymological English dictionary,* containing approximately 40 000 entries, was published in 1721. Bailey was energetic in adding new words (including dialect words, taboo words, and phrases and idioms), borrowing entries from previous dictionaries (principally Kersey's), and systematically giving etymologies. When Bailey could not see a way of improving one of Kersey's definitions, he simply copied it. His etymologies are fuller than those of his predecessors, but reflect the limitations of historical linguistic knowledge of the time. Bailey was not an original scholar in etymology. Instead, he relied on

the work of others, in particular Stephen Skinner's *Etymologicon linguae Anglicanae* (1671), which had also been used in creating previous dictionaries. Bailey catered to the needs of readers of literature of the past by giving explanations of obsolete words used by Shakespeare, Spenser, and Chaucer. Bailey's work, advertised as being "as well for the Entertainment of the Curious as the Information of the Ignorant, and for the Benefit of young Students, Artificers, Tradesmen, and Foreigners," established itself as the standard English dictionary for the early 18th century and went through 30 editions, the latest being published in 1802.

In 1730, Bailey, aided by some collaborators, brought out an enlarged edition of his 1721 dictionary, a folio volume containing 48 000 entries, under the title *Dictionarium Britannicum*. Despite being larger than any of its predecessors, this work is remarkable not least for cutting out many of the fanciful and unused words that figure prominently in older dictionaries in the 'hard words' tradition. It represents a workmanlike attempt to provide a practical inventory of the lexicon of English. At last, lexicography was coming close to fulfilling Mulcaster's 1582 dream of gathering "all the words which we use in our English tung . . . into one dictionary." Another 150 years would pass before the theoretical problems confronting this ambition were addressed (by Murray in the introduction to the *Oxford English dictionary* (*OED*) and subsequently by corpus-based studies of the lexicon). The belief that the lexicon of a language is a finite set is very strong: the fuzziness of the boundaries of that set and the dynamic nature of the lexicon (with new coinages abounding in ordinary usage) have not always been recognized. The *Dictionarium Britannicum* contains many discursive remarks, some more relevant than others, and a list of proverbs. By creating two (actually, more than two) dictionaries at different price points, and thus effectively competing with himself, Bailey began a long tradition in dictionary publishing of adapting, expanding, and abbreviating basic lexicographical material in order to cater to the different needs of different user groups.

Samuel Johnson wrote his *Plan of a dictionary of the English language* in 1747, although the dictionary was not published until 1755. While it was in preparation, another new dictionary appeared, Benjamin Martin's *Linguae Britannica reformata* (1749). This work is important, representing the first attempt to order the senses of a word in a principled way, starting with the most basic sense and working systematically through figurative and derived senses. Martin also acknowledged the impossibility of 'fixing' the language: "The pretence of fixing a standard to the purity and perfection of any language . . . is utterly vain and impertinent, because no language as depending on arbitrary use and custom, can ever be permanently the same, but will always be in a mutable and fluctuating state."

Johnson's dictionary appeared in 1755. This magnificent work is remarkable on many grounds, not least its literary quality, the crisp and authoritative tone of its definitions, and its occasional flashes of idiosyncratic humor. The preface not only agrees that a living language cannot be fixed – in contrast to the intention stated in the 1747 plan – but also touches briefly on nearly all the major theoretical and practical issues of lexicography, such as defining techniques, light verbs and phrasal verbs, *-ing* forms, conventional metaphors, vagueness of word meaning in use, and others. Some of these issues were not seriously discussed again until the 20th century. Johnson wrote about the goal of 'fixing' the language: "When we see men grow old and die . . ., we laugh at the elixir that promises to prolong life to a thousand years, and with equal justice may the lexicographer be derided who . . . shall imagine that his dictionary shall embalm his language." Johnson, however, still saw it as a major part of the lexicographer's task to make value judgments, offering citations as authorities for good usage and selecting quotations from writers whom he regarded as "masters of elegance and style," although it was sometimes necessary to deviate from this principle: "Words must be sought where they are used."

Johnson conscientiously treated the scientific, medical, and technical vocabulary of his day. Many of these entries are largely incomprehensible to a modern reader without special training. It is remarkable how greatly the framework of scientific vocabulary changed between 1755 and 1878 (the year in which the first fascicle of the *OED* was published). The majority of Johnson's scientific definitions and citations represent an alien, vanished world, whereas the scientific entries in the *OED* are for the most part recognizably part of our familiar modern conceptual universe, even where the details have been refined and altered during a further century of scientific research. Johnson deliberately excluded vogue words, ephemeral slang, and the jargon of commerce and industry: "This fugitive cant, which is always in a state of increase or decay, cannot be regarded as any part of the durable materials of a language, and therefore must be suffered to perish with other things unworthy of preservation." Modern dictionary publishers take a different view, preferring to present fugitive cant as an index of the state of the language or of the world. The word 'alchymy' is defined in Johnson's 1755 *Dictionary* as follows:

ALCHYMY, The more sublime and occult part of chymystry, which proposes, for its object, the transmutation of metals, and other important operations.

There is nothing more dangerous than this licentious and deluding art, which changeth the meaning of words, as *alchymy* doth, or would do, the substance of metals, maketh of anything what it listeth, and bringeth, in the end, all truth to nothing. *Hooker*

O he sits high in all the people's hearts;
And that which would appear offence in us,
His countenance, like richest *alchymy*,
Will change to virtue, and to worthiness.
Shakesp. J. Caesar

Princes do but play us; compared to this,
All honours mimick, all wealth *alchymy.*
Donne

2. A kind of mixed metal used for spoons, and kitchen utensils.

The golden colour may be some mixture of orpiment, such as they use to brass in the yellow *alchymy.* *Bacon*

White alchymy is made of pan-brass one pound, and arsenicum three ounces; *or alchymy* is made of copper and auripigmentum.
Bacon's Physical remains

They bid cry,
With trumpets regal found, the great result:
Tow'rds the four winds, four speedy cherubim
Put to their mouth the sounding *alchymy*,
By herald's voice explained.
Milton's Paradise lost, book 2

The 19th Century: Walker, Richardson, Ogilvie, and Chambers

Toward the end of the 18th century, English lexicographers began to pay increasing attention to pronunciation. Building on foundations laid by Thomas Sheridan's two-volume *General dictionary of the English language* (1780), John Walker created a *Critical pronouncing dictionary and expositor of the English language* (1791), which was often bound together in one volume with Johnson's dictionary. In the 1820s and 1830s, the main activity in English-language lexicography took place in the United States, in particular with the ferocious 'dictionary war' fought out between the Anglophile Joseph Worcester and the Anglophobe Noah Webster (*see* **American Lexicography**).

The most important lexicographical work in England between Johnson and Murray was a *New dictionary of the English language* (1836–7) by Charles Richardson (1775–1865), which first appeared in installments as part of the *Encyclopaedia Metropolitana* from about 1818 onward. Richardson was a believer in the now-discredited theories of John Horne Tooke (1736–1812), who assigned a central role to nouns and verbs and believed that other parts of speech and indeed inflections are derived from either a noun or a verb. He also believed that longer words are derived from shorter ones beginning with the same letters, so that *barn, baron, barge, bargain, bark,* etc. are all derived from *bar* in the sense of 'a defense.' He reached these remarkable conclusions not by painstaking historical philological research, but by introspection. Tooke's more practical disciple Richardson believed that the meaning and use of a word should be conveyed through a selection of well-chosen citations rather than by definitions. Richardson's dictionary offers minimal definitions and few sense distinctions, but a wealth of citations for each word. His energy in collecting these citations was immense. If only for this reason, his work was highly valued by Murray, editor of *The Oxford English dictionary.*

The 19th century also saw the influence of American lexicography on British dictionaries, owing much to Webster. The best of these is the two-volume *Imperial dictionary: English, technical and scientific* (1850) by John Ogilvie (1797–1867). As its title suggests, it included technical and scientific vocabulary, including words that were to be left out of the *OED*, no doubt under the influence of Dean Trench, whose interests lay in the Reformation origins of the Anglican Church and contemporary antidisestablishmentarianism. A one-volume edition appeared in 1886, edited by Charles Annandale. Popularly known as Annandale's Ogilvie, its official title was *A concise dictionary of the English language*.

No survey of 19th-century English lexicography would be complete without mention of the five-volume *English dialect dictionary* (1898–1905) by Joseph Wright (1855–1930). This heroic work is based on Wright's own research and on materials collected by the English Dialect Society, collecting from every part of England vast numbers of traditional rural dialect terms, many of which have now vanished. Its evidence has been invoked to shed light on the origins of puzzling terms in other varieties of English – for example, American *bodacious* (Wright records *boldacious*) and Australian *fair dinkum* (which Wright found in Lincolnshire, meaning 'a fair share of the work').

The Oxford English Dictionary

In 1857, Dean Richard Chenevix Trench (1807–1886) read to the Philological Society in London a paper entitled 'On some deficiencies in our English

dictionaries.' Trench pointed out that many words used by Sir Thomas More and other Reformation writers had not yet found their way into any dictionary. To a modern reader, Trench's insistence that an English dictionary should include an exhaustive inventory of 16th-century ecclesiastical terminology, but exclude the new-fangled terminology of science and medicine, may seem rather odd, especially when we consider the advances in knowledge that had taken place in the first half of the 19th century, with accompanying changes in words and their meanings. Nevertheless, Trench's powerfully argued paper played a key role in persuading the Philological Society to give its backing to *A new English dictionary on historical principles*, as the project was called until it was rechristened *The Oxford English dictionary*, from 1895 unofficially, and officially in 1933. Trench took the view that the first duty of lexicographers is to compile an exhaustive historical inventory of all the words of the language. Definitions, etymologies, pronunciations, grammatical labels, citations, etc. play a secondary role. Distinguishing correct and incorrect usage and good words from bad, which Johnson saw as a central duty of lexicography, were no longer a major part of the task. The approach is robustly empirical and descriptive.

In the following year, 1858, the Philological Society appointed an editor for this proposed dictionary, Herbert Coleridge (1830–1861), and volunteers began to collect citations from literature. Tragically, Coleridge died of tuberculosis at the age of 30, less than 3 years after his appointment. He was succeeded by Frederick Furnivall (1825–1910), a man of many talents. Among other things, he founded the Early English Text Society, which brought out editions of previously unpublished medieval texts, without which the early histories of English words that are among *OED*'s distinctive features could not have been written.

In 1878, after 20 years of desultory citation collection, the dictionary project had fallen into desuetude. James Murray (1837–1915) was then appointed editor. Murray, a self-educated Scottish schoolmaster, was not only a fine scholar, but also a man of tremendous vigor and focus. He collected up the Society's citation slips, such as they were, found new readers (some of whom were to devote the rest of their lives to the dictionary), issued new instructions, and assembled a team of editors to work with him on sorting the slips and drafting definitions in a large shed in the back garden of his house in Oxford, which he christened 'the Scriptorium.' The first fascicle of the dictionary was published in 1884. Murray successfully resisted attempts by Professor Benjamin Jowett, Master of Balliol, to rewrite his Introduction, and he also resisted pressures from the publisher to cut corners and speed up the rate of production. The very thoroughness with which Murray worked threatened the project, however – there was no prospect of his completing the work in his lifetime. A solution was eventually found in the appointment of a second editorial team, led by Henry Bradley (1845–1823), and subsequently a third and fourth team, led by William Craigie (1867–1957) and C. T. Onions (1873–1965), respectively. Murray had instructed all of the principals of these teams and, although each team worked independently, there was constant correspondence between them and Murray. The other principals bowed to Murray's judgment on many but not all matters. This arrangement resulted in successful completion of the whole dictionary in 1928, despite the death of Murray in 1915, and it ensured remarkable homogeneity. In 1933, a supplement was published, containing new words and corrections, and the surviving lexicographers dispersed. Already while working on the last few letters of *OED*, Craigie had set up the *Dictionary of the older Scottish tongue* in Edinburgh in 1921 (*see* **Scots Lexicography**) and in 1925 had decamped to Chicago to take up a professorship in English literature and to edit the *Dictionary of American English* (*see* **American Lexicography**).

The first edition of *OED* is an exhaustive inventory of the words of English (over 600 000 entries, including even 'hapax legomena' from older literary texts), with a detailed historical record of the morphological and semantic development of each one. Its great strengths include its 1.8 million citations (no word is included without citation evidence), its etymologies (informed by the great advances in Indo-European scholarship of the 19th century and subsequent work in comparative lexicology), its magisterial definitions, and the skilful arrangement of senses on historical principles. It is not a dictionary that aims to give an account of the present-day conventions of word meaning. Instead, *sub specie aeternitatis,* it records the earliest meanings and subsequent development of each word. Among Murray's many achievements, mention should be made of his typography. The delight of consulting *OED* is enhanced by the judicious mix of fonts, weights and sizes of type, and the page layout, a beautiful balance between visual clarity and economy of space.

The 20th Century

In four volumes, between 1972 and 1986, a supplement to *OED* was published, edited by Robert Burchfield (1923–2004), adding new words and new senses to the historical record and making many further

corrections. The supplement and the original work, integrated as an electronic database, with support from International Business Machines Corp. (IBM) and from the University of Waterloo in Ontario, Canada, were published in 20 volumes as the *OED, 2nd edn.*, in 1989. The number of citations in this second edition rose from 1.8 million to over 2.4 million. A third edition of *OED*, taking full advantage of computer technology, is currently in preparation. This is a thoroughgoing recension of every aspect of the dictionary, under the editorship of John Simpson, with a large and distinguished team. It is expected to double the size of the second edition and is being published on line in quarterly installments. At the time of writing (2004), the online version of *OED* consists of the third edition for letters M, N, O, and part of P, and the second edition for the rest. New entries and new senses are added elsewhere in the alphabet as soon as they have been fully researched and edited.

In 1933, the two-volume *Shorter Oxford English dictionary,* edited by C. T. Onions and G. W. S. Friedrichsen, was published, an abridgement achieved largely by dramatically reducing the number of citations. In 1993, a completely new edition of the *Shorter* was published, edited by Lesley Brown. This was the first systematic recension of *OED*'s definitions. The vocabulary of the late 20th century was systematically redefined, many new words were added, and the Victorian and imperial biases of the original *OED* and the 1933 *Shorter* were corrected. The fifth edition was published in 2002, with the addition of around 3000 new words and senses and a new and innovative typographical design by Paul Luna.

Dictionary publishing in 20th-century Britain saw a profusion of practical one-volume dictionaries. Five main strands may be distinguished. The mainstream consists of monolingual dictionaries for adult native speakers, of which more later. Another major strand has consisted of dictionaries for non-native speakers of English (*see* **Learners' Dictionaries** and **Idiom Dictionaries**). A third strand consists of dictionaries for children – in particular, schoolchildren. Some English school dictionaries are no more than abbreviated or simplified versions of a mainstream dictionary, in some cases with added pedagogical features such as vocabulary-building exercises and expanded explanations of simple aspects of grammar such as the parts of speech. There could be no better example of 'cramming a quart into a pint pot' than a school dictionary. On the one hand, teachers argue that schoolchildren demand full coverage of vocabulary, with plenty of examples, and that they react negatively to any simplification that smacks of 'talking down'; on the other hand, a school dictionary should be light in weight and clear in layout, with plenty of white space on the page (extrapolation of points made in focus groups during the planning of *Collins school dictionary*, 1989). One of the most successful pedagogical English dictionaries is the *Heinemann English dictionary, 4th edn.* (1995), based on an Australian original compiled by English teachers. This work achieved wide vocabulary coverage in a lightweight volume, in part by the use of small-size type, presumably not a problem for sharp-eyed youngsters. The explanations are traditional, but in language judged suitable for children; it owes little to traditional lexicographese. A completely different approach was taken by *Collins school dictionary* (1989), which aimed in particular to offer help with language encoding, i.e., to help children to use newly learned words correctly, by putting the target word into context, thus: *If you* ***incite*** *someone to do something bad, you try to persuade them to do it.* This defining technique was inherited from the Cobuild dictionary project, also funded by Collins in the 1980s (*see* **Learners' Dictionaries; Definition**).

A fourth strand consists of dictionaries of slang, argot, cant, and informal English (*see* **Slang Dictionaries, English**), alongside which must be set the many more or less scholarly, more or less jocular representations of the vocabulary of particular localities. An example of the best of the latter, combining scholarship with light-hearted readability, is Michael Munro's *The complete patter* (2001), a collection of contemporary Glasgow words and phrases.

Finally, mention must be made of the hundreds of dictionaries of special subjects, ranging from medicine, science, and philosophy to chess, cricket, and baseball. Special-subject dictionaries differ from mainstream dictionaries in offering comparatively discursive explanations of terms and concepts, rather than focusing more strictly on the meaning and use of a word in the language. We conclude this section by discussing briefly other dictionaries that have shaped public awareness in Britain of the lexicon in the 20th century. For reasons of space, many important works – for example, the *Longman dictionary of the English language, the Reader's Digest dictionary,* and the *Encarta dictionary* (1998) – must be passed over in silence.

The Chambers brothers, William and Robert, founded their nonfiction publishing house in Edinburgh in 1819, issuing among other works a great encyclopedia, a series of practical information handbooks, and a weekly journal that achieved a circulation of 80 000. It was inevitable that sooner or later they would add a dictionary to their titles. The first edition of *Chambers' dictionary of the*

English language (1861), edited by A. J. Cooley, was the first in a long line of Chambers' dictionaries. Its successors, issued from 1901 onward for nearly 90 years under the title *Chambers' Twentieth Century dictionary* (Thomas Davidson, ed., 1901) and subsequently as *Chambers' English dictionary* and *The Chambers dictionary*, established the Chambers' dictionaries as an institution beloved of compilers and solvers of crossword puzzles and players of Scrabble, on account of the extraordinarily rich word list, gleaned not only from standard sources but also from Scottish dialects, archaisms, technical terms in obscure pastimes such as cribbage, and, of course, slang. *The Chambers dictionary* is still a wonderful ragbag of English word forms, mixed with a solid practical inventory of the language, in which definitions are pared to a minimum and little space is wasted on examples. Sadly, however, some of the rare and more unusual archaic and dialect words and senses have been removed in recent editions. Davidson's successors, the brothers William and Liddell Geddie, enlivened the pages of the dictionary with occasional dry witticisms, many of them cleverly encapsulating colloquial English usage. By the 1990s, pragmatism had prevailed, historical principles were abandoned (so that the first definition of ***camera*** is now 'the photographer's apparatus' rather than 'a small room' or 'the treasury of the papal curia'), and some of the more exuberant terms and definitions (for example, ***boy***, meaning 'champagne,' a term redolent of Oscar Wilde and his circle), along with many of the witticisms, were excised. In the 1998 edition, the tradition of very occasional elegant or sharp witticisms was revived, insofar as political correctness permits. The following list shows some characteristic entries in various editions of *Chambers' Twentieth Century dictionary*:

éclair, a cake long in shape but short in duration
jaywalker, a careless pedestrian whom motorists are expected to avoid running down
kazoo, a would-be musical instrument
middle-aged, between youth and old age, variously reckoned to suit the reckoner
noose, a snare or bond generally, especially hanging or marriage
sea-serpent, an enormous marine animal of serpent-like form, frequently seen and described by credulous sailors, imaginative landsmen and common liars
vamp, a featherless bird of prey

The most popular and widely used one-volume reference dictionary in Britain in the 20th century and today is undoubtedly the *Concise Oxford dictionary* (*COD*), the first edition of which (1911) drew on *OED* up to the alphabetical point where the editors, H. W. Fowler (1858–1933) and his brother Francis (1870–1918), overtook Murray and his colleagues. Despite its subtitle '*of current English*,' the definitions in the Fowlers' *COD* are mostly arranged in historical order, following *OED*, but otherwise its lexicographical organization and explanations are by no means slavishly derivative of *OED*. Fowler used sense numbers to lump together short definitions into major sense groups, rather than numbering each discrete and substitutable meaning statement separately, as is done in *OED* and many other dictionaries. This, coupled with exemplification by superordinates and other techniques, had the effect of representing the dynamic and variable nature of word meaning more accurately, albeit less crisply, than a discrete sense numbering system. Henry Fowler went on to compile *A dictionary of modern English usage* (1926), a widely cited and authoritative, though sometimes eccentric, reference book giving guidance on the usage of modern English. In 1996, R. W. Burchfield, having completed his work on editing the *OED new supplement*, published *The new Fowler's modern English usage,* which is much more than a new edition – it is a completely new guide to standards in English by an authoritative figure.

The *Concise Oxford dictionary* has remained a perennial bestseller, although subsequent editions range from minor updates to almost completely original works (in particular, the sixth edition of 1976, the eighth edition of 1990, and the tenth edition of 1999), in which only the title remains unchanged. The sixth edition completely updated the vocabulary coverage and for the first time paid serious attention to the language of science and technology. The eighth edition abandoned historical principles and put the modern meaning first. The tenth edition was a derivative of the 1998 *New Oxford dictionary of English* (see later).

The first edition of *Collins English dictionary* was published in 1979. The three principals were Patrick Hanks (who had previously edited *The Hamlyn encyclopedic World dictionary*, 1971, a Briticization of the *American College dictionary*), Laurence Urdang (an American lexicographer who had previously been managing editor of the *Random House dictionary*, 1966), and Alan Isaacs (editor of *The Penguin science dictionary*, 3rd edn., 1966, and subsequent editions). *Collins English dictionary* aimed to bring the best features of American 'college-size' dictionaries to the British and non-American world public. In this it was remarkably successful, establishing itself as a rival to the more literary *Chambers' Twentieth Century dictionary* and the smaller *Concise Oxford*

dictionary. The larger one-volume monolingual dictionaries in America are roughly equally divided between those compiled on historical principles (*Merriam Webster*, *New World Webster*) and those compiled on synchronic principles, i.e., they place the modern meaning first (*Funk and Wagnall*, *American College dictionary, Random House*, *American Heritage dictionary*). *Collins* placed itself firmly in the latter camp. Until 1979, all the leading British one-volume dictionaries (principally *Chambers'* and *Concise Oxford*) were compiled on historical principles. Now, the reverse is the case. Because word meaning is rather unstable, so that many English words have changed their main meaning, in some cases more than once, this simple reversal of the order of definition affects thousands of entries and makes dictionaries much less baffling to the general public. *Collins* also avoided the etymological nesting of defined entries (i.e., unlike the *Chambers'* and *Oxford* one-volume dictionaries of the time, it did not list ***carnation*** under ***carnal,*** even though both words are derived from Latin *carne* 'flesh'). It also avoided the forests of abbreviations that had become conventional, especially in etymologies. Like the *American College dictionary*, it took the view that a dictionary should be a kind of 'collective cultural index' and that names of famous people and places are part of the language, items of common knowledge that belong in a dictionary. Both *Oxford* and *Collins* created a family of smaller dictionaries at different price points, derived from their principal one-volume works. *Collins* had in fact established itself as a publisher of popular small dictionaries as early as 1902, with the *Collins English Gem*.

Until the advent of machine-readable corpora and electronic concordancing tools, lexicographers were starved of evidence as to how words are actually used. Even lexicographers working with large citation files found that citation readers tend to focus on rare and unusual words and senses, while ignoring examples of common, everyday usage. In the preface to the first edition of *Collins English dictionary* (1979), the editor (Hanks) argued that "the lexicographer . . . must have a deep understanding of the terms he is defining. A vast citation file is no substitute for the judgement of the trained lexicographer." The first of these points is uncontroversial: cricketing definitions written by noncricketing Americans, or baseball definitions written by non-ball-playing British lexicographers, bear out the fact that if you do not know how to play the game, you cannot define its terminology. However, subsequent events have shown that the second point was specious. Certainly, trained intuitions are needed for the interpretation of evidence, but the practice of using intuitions to invent evidence is a different matter. One of the main findings of corpus linguistics since the late 1980s has been that the regularities governing word use are more regular, and the irregularities more irregular, than predicted in the dictionaries and linguistic theories of the 1960s and 1970s. Invented examples all too often disregard the unspoken and unformulated conventions that govern normal usage; in other words they distort the regular usage of the very words that they are trying to explain. Capturing those regularities is still a major challenge for English lexicography, and American lexicography has yet to take the challenge seriously at all. This challenge was first met in the British dictionaries for foreign learners of English (*see* **Learners' Dictionaries**). *Collins Cobuild dictionary of the English language*, 1st edn. (1987) is corpus-driven and owes comparatively little to the accretive tradition of English lexicography. Subsequently, two pre-existing English learners' dictionaries (*Longman dictionary of contemporary English* and *Oxford advanced learners' dictionary*) were to be thoroughly revised to take account of corpus evidence, and new corpus-based learners' dictionaries were also published by Cambridge University Press and Macmillan.

Oxford University Press first responded in 1998 to the challenge of corpus evidence with *The New Oxford dictionary of English* (*NODE*); the second edition was published in 2003, retitled *The Oxford dictionary of English* (*ODE*). This work combines the evidence of the British National Corpus with citations for new words and senses collected by the Oxford Reading Program. The second edition drew on the newly created Oxford English Corpus. It also adopted a new organization of definitions, grouping related senses together rather than treating them as if they were independent, mutually exclusive semantic entities. It, too, eschewed historical principles and places the modern meaning first. Unlike *Collins English dictionary*, which makes a similar claim but is not corpus-based, *NODE*/*ODE* has evidence to support its claims about the modern meaning of each word. Reviving and expanding the Fowlers' organizing principle and applying it to the findings of corpus analysis, *NODE*/*ODE* identifies one or more 'core senses' of each word and then uses a system of subparagraphs and bullet points to show how conventional figurative, grammatical, and other exploitations are related to the core sense (see the following examples), drawing on the findings of modern research into prototype theory and stereotype theory. Definitions and examples are corpus based and focus on normal usage; this dictionary also pays more attention than do its rivals to local grammar

and lexical syntax. For example, it draws attention to important points of phraseology by highlighting them in examples, and it records the third valency of verbs (adverbials of direction, place, manner, etc.) insofar as this affects the meaning or normal usage of the word, so that, whereas standard American desk dictionaries record only that ***put*** is transitive (neglecting the obligatory adverbial), *NODE/ODE* says "with obj. and adverbial." Fuller information about the methodology of *NODE/ODE* is given in the introduction in each edition. Entries from *The (New) Oxford dictionary of English* (1998 and 2003) are treated as follows:

> **backbone**. . . **noun** the series of vertebrae in a person or animal, extending from the skull to the pelvis; the spine.
> ■ figurative the chief support of a system or organization; the mainstay: *these firms are the backbone of our industrial sector.* ■ [mass noun] figurative strength of character: *he has enough backbone to see us through this difficulty.*
> **bankrupt** . . . **adjective** (of a person or organization) declared in law unable to pay their debts.
> ■ figurative completely lacking in a particular good quality or value: *their cause is morally bankrupt.*
> **cocoon** . . . **noun** a silky case spun by the larvae of many insects for protection as pupae
> ■ a similar structure made by other animals
> ■ a covering that prevents the corrosion of metal equipment ■ something that envelops or surrounds, especially in a protective or comforting way: *a cocoon of bedclothes* figurative *a warm cocoon of love.*

English Spelling: Rationale

J Mountford, University of Southampton, Southampton, UK

© 2006 Elsevier Ltd. All rights reserved.

The Standard Orthography of English (SOE) is the most widely used writing system in the world, and an enormous educational effort goes into teaching it and, of course, learning it. Linguistics has not so far made the massive contribution to the efficacy of this effort that might have been expected: the study of graphology has lagged behind that of phonology, grammar, semantics, and other aspects of language, and applied linguistics has been more concerned with new orthographies than with old ones.

Writing System, Spelling, Orthography

The term 'writing system' has been used variously by linguists and has not always been distinguished from 'spelling system,' although it is clear that a writing system like SOE has components that lie outside the spelling system – most obviously, punctuation. In addition, there are writing systems that are not at all like SOE. Pitman's shorthand, for instance (or Gregg shorthand), looks quite different, and is quite different in its spelling system (e.g., no digraphs, homophones not distinguished) as well as in its script (the written shapes and the spatial disposition of its graphemes). This example points to another aspect of writing systems: namely, that there is more than one functional kind of writing system. Pitman's shorthand is a stenography, a special-purpose writing system. SOE, by contrast, is a general-purpose writing system, a class of writing system for which 'orthography' is an appropriate name.

The Basis of a Shared Rationale

Two Prongs of Spelling Analysis

A rationale of English spelling should enable teachers, learners, and people in the community (parents, for example) to give a rationale for the spelling of particular words – a 'spelling analysis'; yet good spellers, including good teachers, are rarely able to help weak spellers in this way.

The structure of the spelling system indicates two lines of attack – two prongs. Both of them derive from the grammar, or 'lexicogrammar,' of the standard form of the language – the first directly (see the section "Graphomorphemics") and the second (see the section "Graphophonemics") indirectly via the phonology (selecting a 'reference pronunciation' appropriate to the language community). Common to both is the mathematical concept of the one-member set, familiar already in the analysis of linguistic structure: in a scale, or rank-scale, of units, each unit (except the lowest) consists of one or more members of the next unit below. Take words and syllables: every word consists of 'one or more' syllables, and in English, words of one syllable, such as *aim* or *guess* are particularly common and are known as 'monosyllables.' This is a familiar example of 'one or more' constituency – though, as

it happens, the syllable, which is essentially a unit of rhythm in the pronunciation (phonology), does not play a leading role in spelling analysis. The unit that **does** play a leading role is not a phonological but a grammatical unit: it is, as the immediate constituent of the word, the lowest unit in the grammatical rank-scale, namely, the morpheme.

Graphomorphemic Segmentation (Morphemes)

In general, every orthographic word consists of a sequence of one or more 'morphemes,' and each morpheme can be said, for the moment, to be realized by a sequence of one or more letters. More often than not, the spelling of a word is the sum of its (grapho) morphemes, and this can be notated quite simply, e.g.:

$$^{o}\text{aim} + \text{ing} \rightarrow {}^{o}\text{aiming}$$
$$^{o}\text{guess} + \text{ed} \rightarrow {}^{o}\text{guessed}$$
$$^{o}\text{in} + \text{de} + \text{cipher} + \text{able} \rightarrow {}^{o}\text{indecipherable}$$

where ^{o} indicates letter(s)/spelling and + indicates a spelling junction with no change in the letters on either side, i.e., a 'plus-junction.'

Consider, however, ^{o}hope/hoping, ^{o}try/tried, and ^{o}hop/hopping: in the inflected forms, the nuclear morphemes; ^{o}hope, ^{o}try, & ^{o}hop, have undergone changes in their spelling, to ^{o}hop-, ^{o}tri-, and ^{o}hopp-, respectively. In each case the change affects the left-hand letter at the spelling junction, and such changes as these can be notated quite simply by a single sign (by × instead of +), since they are mutually exclusive:

$^{o}\text{hope} \times \text{ing}\ {}^{o}\text{hoping} \rightarrow$	by E-deletion (left-hand letter, terminal E, deleted)
$^{o}\text{try} \times \text{ed}\ {}^{o}\text{tried} \rightarrow$	by Y-replacement (left-hand letter, terminal Y, replaced by ^{o}i)
$^{o}\text{thin} \times \text{est}\ {}^{o}\text{thinnest} \rightarrow$	by Consonant-Doubling (left-hand letter, Terminal-Consonant, doubled)

These changes, which are not matched by changes in the phonology, are rule-governed: the incidence of plus-junctions and change-junctions is conditioned by the consonant and vowel categories of letters on either side of the junction.

Inflectional junctions provide a model for post-nuclear junctions in general. That is to say, most derivational junctions fall into the four 'core junction' cases: plus-junction (the most common) and the three kinds of change-junction, E-deletion, Y-replacement, and Consonant-Doubling (the least common). Consonant-doubling is less frequent than the other two changes because it is confined to nuclear morphemes, whereas E-deletion and Y-replacement, together with plus-junction, operate routinely all along post-nuclear strings. For instance:

$$^{o}\text{fate} \times \text{al} + \text{ity} \times \text{es} \rightarrow {}^{o}\text{fatalities}$$
$$^{o}\text{rig} + \text{id} + \text{ify} \times \text{ed} \rightarrow {}^{o}\text{rigidified}$$
$$^{o}\text{nat} + \text{ion} + \text{al} + \text{ize} \times \text{ate} \times \text{ion} + \text{s} \rightarrow {}^{o}\text{nationalizations}$$

It is useful to group all post-nuclear affixes together as 'postfixes' to balance pre-nuclear 'prefixes.' 'Postfix' provides a much-needed inclusive term subsuming both 'suffix' (i.e., 'derivational suffix') and 'inflection.' By no means all spelling phenomena at post-nuclear boundaries are accounted for by these core spelling junctions, but they provide a solid platform of regularity from which to address other cases.

As to pre-nuclear boundaries, plus-junctions predominate again, but the core change-junctions of postfix boundaries are replaced by Consonant-Assimilation change-junctions at prefix boundaries, once again affecting the left-hand letter at the junction: note the changes to the prefix ^{o}ad- in ^{o}affection, ^{o}aggregate, ^{o}annotate, ^{o}assume, ^{o}attract (before vowels, only the base form ^{o}ad- is found, e.g., ^{o}adopt, ^{o}adumbrate).

Graphophonemic Segmentation (Symbols)

Graphophonemic segmentation is not so much a splitting down as a grouping together of letters. It can therefore be fittingly shown by the simplest notation of all, underlining: ^{o}c a t, ^{o}ea ch, ^{o}sh ee t, ^{o}e ch o. The underlined groups of letters (including groups of one) correspond to phonemes in the pronunciation; they are 'graphophonemic symbols' or, less ponderously, 'symbols.' In general, it is not difficult to assign, in a principled way, every letter in the spelling of a word to a symbol (it just requires practice). The most frequent length of symbol is one letter, but as a class there are, of course, only 26 of these (the number of letters in the alphabet of SOE). The largest class of symbol is the two-letter class, embracing the familiar pedagogical consonant 'digraphs' like ^{o}ch, ^{o}sh, together with vowel symbols like ^{o}ea, ^{o}ai, consonant symbols like ^{o}kn, ^{o}mb, vowel symbols like ^{o}aw, ^{o}al, and double-letter symbols like ^{o}tt, ^{o}oo. These and other varieties of two-letter symbol are not always included under pre-theoretical 'digraph.' Three-letter symbols are mostly, and four-letter symbols are exclusively, vowel symbols like ^{o}catch; ^{o}beauty; ^{o}would; ^{o}high; ^{o}straight.

Symbol segmentation is not, however, a familiar exercise, either for the educated in general or even for educators. Two important reasons for this, inherent in the spelling system (rather than in the education system) are: (**a**) discontinuous symbols – the symbols

just illustrated are all continuous, but terminal-E' symbols, as in °take, °literate, °freeze, °sympathize, °house, °cute; introduce limited but textually frequent discontinuity, and (**b**) mixed symbols – while vowel letters barely have a role in consonant symbols (think of °guest, °guy), consonant letters have an evident role in vowel symbols (°would, °high, °straight). It can be seen, then, that symbols have structure in terms not only of letter places but also of letter categories.

One effect of concentrating on symbols and their structure is to shift the individual letters and their traditional 'sounds' from center stage as units of correspondence. The unit of phonemic correspondence in the spelling system of SOE is the graphophonemic symbol of one, two, three, or four letters, and the 26 letters are the irreducible combinatory elements out of which symbols are constructed. Each letter has a distinct pattern of behavior in terms of the symbols it enters into and the roles it plays in those symbols (consider, for example, the letters °h, °t, and °w in the symbols of °hat, °that, °what, °who, °watch, °wrath, °th aw). That behavior includes, in each case, acting as a one-letter symbol. Encouragingly, in ordinary texts, one-letter symbols predominate, by about four to one, over complex symbols. Looked at another way, one symbol in five is complex.

It is symbols, then, that enter into correspondence with phonemes: a 'graphophonemic correspondence' is a symbol matched to a phonemic value. For example: °b — /b/ is a primary correspondence, so is °ch — /ch/ ("symbol CH with the value [tš]") as in °church; °ch — /k/ as in °school is a secondary correspondence). With correspondences, two more inherent reasons emerge for literate people's reluctance to explore the spelling system. These are: (**c**) many symbols have more than one value, for example, °ch and most vowel symbols; and (**d**) many high-frequency words, including both 'function' words and 'content' words, contain not merely secondary but tertiary correspondences (e.g., °any, °busy, °come, °England, °friend, °great, °have, °of, °one, °said, °who), with limited or very limited distributions. As with letter structure, so with value range: compared to vowel symbols, consonant symbols are relatively straightforward.

Symbol segmentation can be viewed as one path toward phonemic analysis. Symbols can be segmented and categorized as vowel or consonant symbols before specific phonemic values are identified; and where standard word pronunciations differ, it is typically in the phonemic value to be attached to a single (simple or complex) symbol. Consonant/vowel category profiles of words provide another solid platform from which to address a familiar language awareness problem — phonemic identification. Without phonemic identification, any rationale of English spelling is incomplete.

Bringing the Two Prongs Together

A grammatical approach to the spelling system dispenses straightaway with the naïve view that letters (one or more) are the immediate constituents of words; it interposes the morpheme. But letters are not the immediate constituents of morphemes either: between morphemes and letters is interposed now the graphophonemic symbol as a unit in a four-rank constituency scale. The same one-or-more relationship holds in turn between words and morphemes, between morphemes and symbols, and between symbols and letters. At the same time, this approach provides a unit of correspondence with the phonemes of the spoken grammar, namely, the symbol, which does not, as the letter does quickly and repeatedly, break down in application. This enables the learner to advance beyond the naïve view that it is just letters that correspond to sounds (°cat, as we all know, is a 'one-to-one' word, but °chat, °cash, °Cath, °catch, °case, °cease, and °caught are not).

Beyond 'monosyllables' (and note that °guessed is a monosyllable homophonous with °guest) there are serious features of English structure to be confronted: two outstanding ones are 'lame' nuclears (like ° fess~ in °confessor, in contrast to °press in °compressor; recall °rigid and °nation, and compare °rigor and °native); and the minimal vowel (shwa twice in °compartment, twice in °depended). But the framework sketched here can be extended to cope with these to provide a rationale of the whole spelling system.

Conclusion

Much more needs to be said about morphemes in this rank-scale, including their stability (greater than in phonology) and their variability (both rule-governed and idiosyncratic). But enough has been said to indicate that there are two complementary, principled approaches to the highly accessible data of English spelling, which can be combined into a single framework. Their application is not unproblematic (nor are they exhaustive of the resources of the spelling system, which include, for instance, capitalization and apostrophes), but the principle that in turn governs them is that morphemes take precedence over symbols. Morphemes have meaning; symbols do not. Spelling analysis must be the servant of meaning.

This implies a change of paradigm, from the traditional 'words, letters, and sounds' paradigm to 'the spelling system as a whole' paradigm, with due attention to linguistic concepts and structures,

terminology, and notation. Educational effort might then pay off, undistracted by notions of absurdity or unanalyzability, obsolescence, spelling reform in the foreseeable future, or computers to the rescue (though computers have their place in developing understanding of the spelling system and how it works). There must be something about SOE – something internal, in addition to external circumstances – that makes it so successful as an orthographic writing system, and nine-tenths of a writing system is its spelling system.

English, African-American Vernacular

P L Patrick, University of Essex, Colchester, UK

© 2006 Elsevier Ltd. All rights reserved.

The term 'African-American English' (AAE) – formerly 'Negro' or 'Black English' or sometimes 'Ebonics' – denotes a range of ethnically distinctive varieties of North American English characteristically spoken by descendants of Africans brought to the Americas under slavery. This broad range includes regional and social dialects (rural Mississippi folk speech, African Nova Scotian English, Standard AAE); isolated contact and creole varieties (Gullah [Sea Island Creole English], Afro-Seminole Creole in Florida, Texas, and Mexico); distinctive oral discourse styles (preachers' rhetoric, political oratory, and slang associated with jazz, gospel, or hiphop); and their literary expressions.

The best known variety of AAE today is African-American vernacular English (AAVE), which is popularly associated with urban culture, working-class and younger speakers, and informal contexts. Contemporary AAVE originated via the Great Migration – the northern urbanization of rural Southern African-Americans that took place between World War I and World War II – and replaced older, post-Emancipation stereotypes of isolated rural dialect speakers, such as the Ex-Slave Elders (Bailey *et al.*, 1991). However, African-Americans collectively speak many varieties of English and other languages: not all use AAVE or participate in vernacular African-American culture (Baugh, 1991, which also surveys labels for the variety and speakers). Many African-American adults are skilled code-switchers; most have competence in standard AAE, which, although lacking nonstandard grammatical features, is yet distinctively and fluently African-American. Of the 36 million African-Americans in the United States (13% of the population), a large but unknown proportion speaks AAVE.

The distribution and functions of AAE are generally obscured by stigmatization and misrepresentations, principally: mistaking AAVE for all of AAE; the belief that AAVE is not a complete, systematic grammatical system (e.g., mistaking adolescent slang for all of AAVE); and the belief that vernacular use of AAVE is incompatible with literacy and mastery of standard American English (SAE). Linguistic

terminology, and notation. Educational effort might then pay off, undistracted by notions of absurdity or unanalyzability, obsolescence, spelling reform in the foreseeable future, or computers to the rescue (though computers have their place in developing understanding of the spelling system and how it works). There must be something about SOE – something internal, in addition to external circumstances – that makes it so successful as an orthographic writing system, and nine-tenths of a writing system is its spelling system.

English, African-American Vernacular

P L Patrick, University of Essex, Colchester, UK

© 2006 Elsevier Ltd. All rights reserved.

The term 'African-American English' (AAE) – formerly 'Negro' or 'Black English' or sometimes 'Ebonics' – denotes a range of ethnically distinctive varieties of North American English characteristically spoken by descendants of Africans brought to the Americas under slavery. This broad range includes regional and social dialects (rural Mississippi folk speech, African Nova Scotian English, Standard AAE); isolated contact and creole varieties (Gullah [Sea Island Creole English], Afro-Seminole Creole in Florida, Texas, and Mexico); distinctive oral discourse styles (preachers' rhetoric, political oratory, and slang associated with jazz, gospel, or hiphop); and their literary expressions.

The best known variety of AAE today is African-American vernacular English (AAVE), which is popularly associated with urban culture, working-class and younger speakers, and informal contexts. Contemporary AAVE originated via the Great Migration – the northern urbanization of rural Southern African-Americans that took place between World War I and World War II – and replaced older, post-Emancipation stereotypes of isolated rural dialect speakers, such as the Ex-Slave Elders (Bailey *et al.*, 1991). However, African-Americans collectively speak many varieties of English and other languages: not all use AAVE or participate in vernacular African-American culture (Baugh, 1991, which also surveys labels for the variety and speakers). Many African-American adults are skilled code-switchers; most have competence in standard AAE, which, although lacking nonstandard grammatical features, is yet distinctively and fluently African-American. Of the 36 million African-Americans in the United States (13% of the population), a large but unknown proportion speaks AAVE.

The distribution and functions of AAE are generally obscured by stigmatization and misrepresentations, principally: mistaking AAVE for all of AAE; the belief that AAVE is not a complete, systematic grammatical system (e.g., mistaking adolescent slang for all of AAVE); and the belief that vernacular use of AAVE is incompatible with literacy and mastery of standard American English (SAE). Linguistic

ideologies comprising such beliefs and attitudes have long obscured AAVE's structure and history and have been complicit in racist social structures. Descriptions of AAVE thus generally address not only synchronic structures but diachronic development, attitudes, and applied (especially educational) issues.

Lexicon

African-American speech diversity may be illustrated with the lexicon. Works on AAE list many thousands of items used almost exclusively or with distinctive meaning by African-Americans (Major, 1994; Smitherman, 1994; Cassidy and Hall, 1985). African-American English is a prolific source of slang and specific registers, from which items pass into general American use, if often late and with distortions. Stereotyping and stigmatization of urban slang by non–African-Americans has contributed to the general devaluation of AAVE as a linguistic system. While speaker competence varies along regional, generational, and social lines, knowledge of even widely shared lexical items (unknown in, or contrasting with, mainstream English) does not guarantee familiarity with grammatical properties of AAVE (Green, 2002). The AAE lexicon is a greater unifying force than AAVE grammar. The number of AAE lexical items with clearly identified African etymologies is significantly smaller than in Caribbean English creoles (CECs) – for example, Jamaican Creole English (Cassidy and Le Page, 1967) or Gullah (Turner, 1949), in which hundreds are attested.

Discourse

Uncensored speech (often judged profane or obscene) is subject to different norms in AAVE than in mainstream American English; items for which normalization, neutralization, and generalization have occurred may differ (Spears, 1998). The stereotypical prominence of uncensored speech, as perceived by non–African-Americans, reflects not only their contemporary social power to censor, but the obsolescence of earlier rules of respectful address and demeanor, enforced on black people by white people. This has resulted in more frequent direct speech (Spears, 2001), including 'dissing', 'reading', and others (Morgan, 1998).

Everywhere in the African diaspora, under slavery, such enforcement spurred development of characteristic modes of indirect speech, ambiguity and speaker agency ('counter-language', Morgan, 1993), e.g., 'signifying', 'marking', and 'loud-talking' (Mitchell-Kernan, 1971). Loud-talking involves direct address and manipulates volume to invoke an audience; marking characterizes targets through direct quotation, which may manipulate features of grammar, phonology, or pragmatics; while conversational signifying attributes "personal characteristics of the target to culturally marked signs" (Morgan, 1998, p. 275). Children and adolescents practice signifying in formalized routines of verbal play known as 'sounding', 'joning', 'snapping', and 'playing the dozens', wittily placing culturally significant emblems (e.g., *yo'mama*) in implausible contexts (Abrahams, 1962; Labov, 1972). African-American English speech events resemble Caribbean ones, like 'busing' (Guyana) or 'dropping remarks' (Barbados), or have pan–African diaspora distribution ('suckteeth', Patrick and Figueroa, 2002).

Syntax

Much early analysis of AAVE grammar contrasted it with both SAE and CECs; recent historical work compares it to Southern White vernacular English (SWVE). Much attention focuses on the AAVE verb phrase, and less on negation, nominal inflection, and pronoun selection (Green, 2002; Rickford, 1999). Major questions include (a) the degree of structural independence of AAVE from general English grammar, (b) evidence for AAVE's historical ancestry and development, and (c) the nature and significance of variation. Grammatical features are more often distinctive, while many phonological features occur in other vernacular English varieties, especially SWVE. Typically, nonstandard features occur more frequently in AAVE, in a wider range of linguistic contexts, while linguistic processes (e.g., rapid-speech reduction rules) are carried further. The nonstandard nature of AAVE is thus gradient, and often exacerbated by comparison to written standard norms.

The AAVE auxiliary system largely mirrors general American English (and so contrasts with CECs). However, main verbs and auxiliaries (*be*, *have, do*) have regular paradigms, without person/number agreement: third singular irregular forms are absent. For auxiliary *be*, the *is* form is generalized to all present persons and numbers (except first singular *am*), and *was* to all in the past. African-American vernacular English carries further a general American English tendency to regularize simple past and present perfect verb forms: they frequently merge in the simple past, although some participial forms are preferred. A few frequent strong verbs use stem forms with past meaning, but past-marking is overwhelming (again, unlike CECs). Future with modal *will* resembles general American English, although the normal phonological reduction to '*ll* is variably extended to complete vocalization and deletion. Question formation optionally involves inverting

auxiliaries and modals. Auxiliaries (only) may also fail to surface in questions, and may invert in embedded questions. The AAVE sentential negator *ain't* appears for standard *hasn't/haven't* or *isn't/aren't*, as elsewhere, but also for *doesn't/don't*. As in CECs, the sentential negator is tense-neutral, appearing for past meanings too.

Fundamental contrasts with other dialects occur for AAVE aspectual markers, which take forms deceptively similar to Vernacular American English auxiliaries (*be*, *been*, *done*, *had*). The complex aspectual system makes distinctions unfamiliar to other English dialects. The case of the habitual invariant *be*, widely taken as emblematic of AAVE, is typically misused or misunderstood by nonnative speakers. Other 'camouflaged' forms, often mistaken for their SAE equivalents, include *had* marking the simple past; the nondirectional *come* to express speaker indignation (Spears, 1982); and a stressed *been* for remote past. With stative verbs, *been* denotes continuity to the present moment; stativity constraints are typical of CECs, where *been* also marks remote past. Less familiar AAVE preverbal aspect markers include the immediate future *finna* (<SWVE *fixing to*), the completive *done*, the resultative *be done*, and *steady* marking an intensified continuative. Although several resemble CEC elements in functions, constraints, and even surface forms, few are patterned identically to any CEC, and some came into being or prominence during the last century: habitual *be* was rare "before World War II and . . . virtually non-existent . . . before 1900" (Bailey, 2001, p. 57).

Although negative concord and negative inversion resemble similar strategies elsewhere, AAVE seems unique among the varieties of American English in requiring concord with indefinite object noun phrases, a feature it shares with CECs. As with verbal *–s*, possessive and plural *–s* may both be absent in AAVE, though less often (respectively, 71% absence compared to 27% and 6% in vernacular Detroit speakers, Wolfram, 1969; absence is significantly greater in CECs). Associative plurals (*Doretha an' (th)em*) resemble CEC plurals with postposed *–dem*, but the AAVE structure (with its mandatory conjunction) occurs in SWVE. Descriptions of generational developments for these complex features are rare (Cukor-Avila, 2001). Pronominal features include pleonastic *it* and *they* in existential constructions. Invariant forms for plural possessives (*yall*, *they*), and occasional object forms for subjects (*us*), represent paradigm levelings that, taken together, are rare to nonexistent in other American English dialects but occur in CECs. The larger issue of modeling AAVE as a (sub-)system *vis-à-vis* general American English remains under-theorized (Labov, 1998).

Phonology

Bailey (2001) surveyed 45 phonological aspects discussed in the literature for either AAVE or SWVE: 19 were shared, 8 were common to AAVE but rare in SWVE (11 were vice-versa), and 6 were pan-English. Several of the oldest established shared features are receding for one or both groups: e.g., loss of intersyllabic /r/ (*hurry*), and long offglides after /a/ (*half* [hæif]). Features that are still vigorous in both varieties, such as glide reduction in /ai/ (*tie*) and /ɔi/ (*boil*), front-stressing (*po'lice*, *De'troit*), or the *pin/pen* merger in [ɛ] before nasals, developed in the late 19th century, when whites and African-Americans worked in contact as tenant farmers. Final consonant cluster reduction, a general English feature, is more frequent in AAVE, significantly before vowels (*firs' apple*).

Features particular to AAVE include shibboleths such as deletion of initial voiced stops /d, g/ in auxiliaries (*I'm (g)onna* /amənə/) and realization of syllable-initial /str/ as /[skr] before high front vowels (*street* [skrit]). Others involve final singleton consonants: reduction and loss of nasality in final nasals (*man* [mæ]) and deletion of word-final single consonants after a vowel (*cat* [kæ], *bad* [bæ:]). Final voiced stops are devoiced and sometimes glottalized (*bad* [bætʔ]).

In recent research on vowel subsystems, recordings of mid-19th century speakers show monophthongal /e/ and /o/ and fully back /u/ and /ʊ/, which contrasts with SWVE and American English generally but resembles CECs. Today AAVE possesses the same vowel phonemes as American English; its mergers and glide reductions all occur elsewhere in American English (Bailey and Thomas, 1998). But African-Americans as a group do not participate in systematic shifts of vowel position – the changes from below – that are characteristic of other dialects (Labov, 2001). Thus /æ/-raising, present in AAVE since the late 19th century, is not integrated into a pattern like the Northern Cities Shift. Several conditioned vowel mergers occur in AAVE and SWVE, but only SWVE reorganizes them into the Southern Shift.

History

The history of AAVE is controversial. Many dialectologists once held an 'Anglicist' position, arguing that AAE showed the same range of variation as comparable white speech (McDavid and McDavid, 1951). This was contested by the early creolist position, which held that a creole developed in colonial America (beyond the Gullah area) and subsequently decreolized, producing current forms of AAVE (Bailey, 1965; Stewart, 1968). Research on variable

realization of the *be* copula and auxiliary (Labov, 1969; Baugh, 1980) noted substantial similarities with CECs that were confirmed by later research using methodological refinements (Rickford *et al.*, 1991; Winford, 1992; Blake, 1997).

This line is opposed by a neo-Anglicist position (Poplack, 2000) drawing on data from Ex-Slave recordings and African American congeners (enclaves in Nova Scotia and Samaná), varieties united under the questionable label, 'Early AAE.' Poplack and Tagliamonte (2001) maintain that AAVE is directly descended from British dialects. Analyses of tense/aspect marking compare Early AAE with historical English dialects and CECs and conclude that nonstandard features of AAVE "were not created . . . but retained from an older variety of English" (Poplack and Tagliamonte, 2001, p. 251).

Such claims remain controversial among variationists and creolists, whose post-1990 research documents a more complex picture of CEC grammars, which neo-Anglicists largely ignore. The historical significance of enclave varieties rests on their conservative nature and representativeness of their ancestors. Singler's studies (e.g., 1998) of transplanted African-American settlers in Liberia constitute crucial evidence for AAVE; they represent many more speakers (16,000 emigrants) and are more typical of contemporary African-Americans. Singler's results, like Rickford's critiques, frequently conflict with neo-Anglicist positions and emphasize compatibility with recent research on CECs. Wolfram and Thomas (2002), in conducting an intergenerational analysis of an isolated Southern community, also reached different conclusions, arguing that the ethnolinguistic distinctiveness of AAE, although temporarily submerged by accommodation to regional dialect norms, still reflects a broader range of contact influences than British dialects, including African and CEC languages.

While early creolist positions have largely been abandoned in strong form, new research locates creole-like features in 'micro-switches' among indigenous early AAVE speakers far outside the Gullah area (Sutcliffe, 2001). Current creolist positions emphasize multiple causation and structural convergence between CEC and other inputs in a complex contact situation. Speakers from CEC-speaking territories predominated among early black arrivals in many American colonies, often predating direct African imports (Rickford, 1997). Through sustained contact with Gullah, African varieties, and British dialects, CEC speakers contributed substrate influences to AAVE grammar, without leading to acquisition of entire creole grammars (Winford, 1997; Wolfram and Thomas, 2002). Such generalized contact scenarios invoke interlanguage restructuring, for example, in the acquisition of syllable-coda consonant clusters (absent in West African inputs), leading to substantial prevocalic consonant cluster reduction. This produced similar results in both AAVE and CECs (but not SWVE) and thus convergent structures, which might have been reinforced by contact between them (Winford, 1997; Wolfram and Thomas, 2002).

Genesis issues are logically divorced from questions of current change, which focus on convergence or divergence with other American English dialects (Fasold, 1987; Bailey and Maynor, 1989). An expansion of data sources and the range of features studied led to findings of post-Emancipation innovations in AAVE phonology and syntax (examples cited previously). Taken alongside evidence of contemporaneous innovations in SWVE and the discovery of recent rapid diversification among mainstream American English dialects in major cities – in which younger African-Americans, who show surprising agreement on nationwide norms, are not participating (Labov, 2001; Thomas, 2001) – these developments demonstrate considerable divergence. However, convergence on other levels certainly continues (plural *–s* and past-marking, Rickford, 1987), while some features display both (present *–s*, Wolfram, 1987). Moreover, many linguists agree that the evidence is incomplete, the database can be improved, and the complexities of change and variation in AAVE, including its relationships to AAE and American English and the social consequences thereof, are far from satisfactorily understood.

English, Early Modern

H Raumolin-Brunberg, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Background

The early modern period (1500–1700) brought several significant changes in the lives of the English people. The most dramatic were perhaps the Reformation, the subsequent dissolution of the monasteries in the 16th century, and the devastating Civil War during the next. Less abrupt phenomena included population growth; changes in the social hierarchy, including greater social mobility; increasing economic activity; a widening world view; and growing national identity.

There were two developments that radically increased the number of written texts. The printing press was introduced into England in 1476, paving the way for subsequent genre diversification and popular writing. The expansion of educational opportunities promoted literacy, although still less than half the men and a third of the women could both read and write, even by 1700.

Good evidence that English had acquired its modern form is that the great literature of this period, such as Shakespeare's plays and the 1611 Bible translation known as the Authorized Version or King James Bible, can be understood by modern readers and listeners despite their archaic feel.

Linguistic Features

Phonology

Understanding Renaissance drama would be more difficult if it were performed using contemporaneous pronunciation, because many Early Modern English (EModE) words were not pronounced the same way as they are today. This divergence largely arises from shifts among the vowels, because changes in the consonant system have been limited.

The well-known series of changes known as the Great Vowel Shift affected long vowels. The origin and course of this development are still in debate, but it is clear that all Middle English (ME) long vowels changed at various times after 1400 (Table 1). The diphthongization of two ME long vowels, /iː/ and /uː/ into /ai/ and /au/, as in *write* and *house*, and the later merger of /eː/ and /ɛː/, as in *meet* and *meat*, left English with four long vowels, /iː, eː, oː, uː/. This inventory was supplemented by /ɒː/, which developed from the diphthong /au/, as in *cause*.

During the early modern period, the ME diphthongs, /iu, eu, au, ai, ou/, were monothongized, becoming /uː, uː, ɒː, eː, oː/, whereas /oi/ and /ui/ remained unchanged, as in *joy* and *boil*. A combination of these and new diphthongs that developed from long vowels resulted in three diphthong phonemes, /ai, au, ɔi/, at the end of the period. The impact of postvocalic /r/ which, among other things, often lowered preceding vowels, also created new diphthongs, when an epenthetic [ə] was inserted between a vowel and [r], as in *fire*. Although there may have been sporadic cases of the loss of postvocalic /r/ in the early modern period, its systematic deletion took place later.

The ME short vowels /i, e, a, o, u, ə/ remained mostly unchanged. A significant change was the southern split of /u/ into two phonemes, /u/ and /ʌ/, e.g., *put* and *cut*.

The consonant system lost the phoneme /x/, which was often spelled <gh>, with its two allophones [x, ç] Its realizations were replaced by vowel lengthening, e.g., *right* or by /f/, as in *enough*. Two new consonant phonemes, /ʒ, ŋ/, developed, and since that occurred, the inventory of English consonants has remained unchanged. The consonant /h/, was very weak and occasionally dropped, as contemporary spellings like <*elmett*> for *helmet* and the excrescent <*h*> in <*hevere*> for *every* show, but there is no evidence of its stigmatization.

Grammar

Many of the grammatical developments originating in the previous centuries continued in EModE, including morphological simplification and the stabilization of word order. On the whole, English acquired its present analytical structure during the early modern period. These developments are perceptible, for example, in the decline of inflectional endings, the

Table 1 Change in long vowels: schematic development

Middle English	*Early Modern English (1500–1700)*		*Present-day English*	
	Early	*Late*		
iː	əi	ai	ai	write
eː	iː	iː	iː	meet
ɛː	ɛː	eː	iː	meat
		iː		
aː	æː	eː	ei	make
uː	əu	au	au	house
oː	uː	uː	uː	food
ɔː	ɔː	oː	əu	boat

Sources: Görlach (1991: 70), Barber (1976: 294).

increasing use of auxiliaries, and the diminishment of inversion. Natural gender, in particular, the distinction between human and nonhuman reference, became an important factor among pronouns. The grammaticalization process created new closed-class elements in several areas of grammar.

Nominal inflection was mostly limited to the plural and genitive *-s* endings, except for some *-en* plurals, such as *brethren*. The case distinction between the nominative and accusative was only retained in the personal pronouns and the pronoun *who*. The personal pronoun paradigm is indeed a good example of an area that underwent significant changes in EModE (Table 2). First, the second-person plural forms *ye/you/your* came to be used in the singular. This process, which had begun in Middle English, gradually ousted the old *thou* paradigm from Standard English, but allowed subtle expression of power relations, politeness, and intimacy before it did. Second, the originally plural nominative *ye* was replaced by the accusative *you*. Moreover, the first- and second-person possessive determiners *mine* and *thine* lost their *-n* ending. The last environment where *-n* was used was the pre-vowel position; e.g., *thine eyes*.

Furthermore, the third-person neuter possessive determiner *its* was introduced into the language around 1600, replacing *his*, which had become affiliated with male human reference as a consequence of natural gender replacing grammatical gender. Human reference also began to constrain the choice of the relative pronoun, when *who/whom* was limited to personal reference and *which* to non-personal reference.

Verbal inflection was also simplified by reducing the present indicative suffixes to one, which in most varieties only encoded the third-person singular. The main suffix in the 16th century was *-th*, as in *he maketh*, which gave way to *-s* in the next century, as in *he makes*. These suffixes were also occasionally used in the plural. The second-person singular suffix *-st* appeared with *thou* but, as mentioned above, this pronoun became rare. The paradigms of strong and irregular verbs were stabilized to a large extent, and the number of verbs with weak conjugation grew.

Table 2 Early Modern English personal pronouns

	Nominative	*Accusative*	*Genitive (Possessive Determiner)*
Singular			
1st	I	me	my, **mine**
2nd	you, **ye**, *thou*	you, *thee*	your, *thy*, **thine**
3rd	he	him	his
	she	her	her
	it, **hit**	it, **hit**	ITS, **it, his**
Plural			
1st	we	us	our
2nd	you, **ye**	you	your
3rd	they	them, **hem**	their

Items in bold disappeared during the early modern period. Items in italics became rare during the early modern period. Item in small caps emerged during the early modern period.

An important phenomenon in the EModE verb phrase was the increasing use of periphrastic forms and auxiliaries at the expense of one-verb groups. Both *have* and *be* occurred in the (plu)perfect tense, but the use of *be* was limited to mutative intransitives, such as *a childe is come*. The aspectual marker, progressive *be* + *ing*, developed during the early modern era, which also witnessed the development of the auxiliary category, consisting of *can, could, may, might, must, shall, should*, *will,* and *would,* as these verbs lost their full-verb properties, such as non-finite forms and the ability to take non-verbal objects. These auxiliaries were employed to express many of the functions the subjunctive had had in earlier English, although the subjunctive did not entirely disappear.

Furthermore, during the 16th century the non-emphatic use of the auxiliary *do* grew rapidly in affirmative statements, but its popularity fell quickly in the 17th century. In contrast, the employment of *do* in interrogative, imperative, and negative declarative sentences found a firm footing in the language.

Alongside the use of *do* in negative declaratives *dos not hinder*, the old verb + *not* structure was common, in particular with the verbs *know*, and *doubt*, as in *I know not* and *I doubte not but*. Multiple negation was frequent until around 1600, as in *he helpes me nat with natheng*.

Although the regular word-order in affirmative statements was SVO, in the first decades of the 16th century it was not uncommon to invert the word order after adverbs such as *then, therefore, thus*, and *yet*. The present-day pattern of inversion after negative adverbs, such as *neither, nor*, and *never,* developed from the late 16th century onwards.

New function words were created through grammaticalization. For instance, new indefinite compound pronouns with personal reference developed, such as the forms in *-body*, e.g., *nobody,* from *no* + *body* 'person'. Similarly, complex prepositions such as *because of* from *by* + *cause* + *of* developed in EModE. Several connectives, for instance, *since, while*, and *because*, grammaticalized in earlier English, acquired new senses in the early modern period.

Lexis and Semantics

The early modern period witnessed large-scale lexical growth through extensive borrowing and expansion of word-formation patterns. The major source

language was Latin, but loans from other languages, in particular French, were also frequent. The extension of English into all areas of life, including science, and the broadening spectrum of genres, styles, and registers created a need for new and more varied vocabulary, which was satisfied with borrowings and native coinages.

This intake of Latinate vocabulary reduced the transparency of the English lexicon by adding a new layer to the already existing Germanic and Romance strata. On the other hand, it provided ample material for the creation of specialist technical terminologies. Not everybody was comfortable with the tremendous increase in Latinate words, as is testified to by the so-called Inkhorn Controversy in the late 16th century, when voices were raised against excessive use of learned borrowings. Dictionary evidence shows that many of these loanwords were short-lived, and it has been estimated that approximately a third of Shakespeare's numerous Latinate neologisms only occurred once.

Loanwords became integrated into the language to varying degrees. Writers occasionally used nearly synonymous word-pairs to make sure that the readers understood the borrowing, e.g., *wepyng and lamentyng*. Inflectional endings such as L *-atus* > E *-ate*, were modified as in *alternate*. Multiple borrowing occurred, and the spelling of older French loanwords could be Latinized, as illustrated by *dout* > *doubt*.

The existing word-formation patterns, affixation, compounding, and conversion, were expanded by borrowing. For instance, among the negative prefixes, the native *un-*, e.g., *unmeet*, encountered four competitors, *a-*, *in-*, *dis-*, and *non-*, e.g., *discontented*.

The biggest problems for understanding EModE texts arise from semantic changes, which range from radical changes in meaning to shifts in nuances. For example, *mete* means 'food' in general and not what we understand by *meat* today, and *an auncient and sad matron* in Sir Thomas Elyot's educational treatise is simply 'an old and trustworthy married woman'.

Linguistic Diversity

Although the presentation of early modern general features may give the impression of linguistic uniformity, we must not forget that there was substantial regional, social, individual, generic, and stylistic variation. Despite the lack of a codified model, the language underwent standardization in terms of focusing and option-cutting, with orthography leading the process. The spellings of early and later texts diverge in general, but barely literate people's private writings contain atypical spellings at all times.

Table 3 The Early Modern English genres in the *Helsinki Corpus of English texts*

Literate genres	Law
	Handbooks
	Science
	Educational treatises
	Philosophy
	Sermons
	History
	Travelogue
	Biography
	Letters non-private
	Bible
Oral genres	Trial proceedings
	Fiction
	Letters private
	Drama
	Diary
	Autobiography

There is no doubt that people spoke their local dialects, but dialectal texts are rare because of the low level of literacy. Drama can offer some information on dialectal usage, and private texts occasionally contain regional features.

As in any society, there were social differences in the language use in early modern England, which was markedly hierarchical. Research on the diffusion of morphosyntactic changes shows that several were introduced by the middling ranks and diffused from the London region to the rest of the country. Changes originating in the spoken language were usually led by women, but men were ahead of women in learned changes such as the loss of the multiple negation. The diversification of genres led to new genre conventions and stylistic variation. The 17 early modern genres included in the *Helsinki Corpus of English Texts* illustrate the broad spectrum of early modern writing (see Table 3). The most formal literate genres such as law, philosophy, and science stand out with Latinate diction and structural complexity both on the sentence and phrase level, whereas oral genres such as fiction and private correspondence often rely on Germanic words and simpler structures.

Introduction

The recognition of Late Modern English as a separate period in the history of the English language is a fairly recent phenomenon. The first linguist to use the phrase appears to be Poutsma, but his (1914) *A grammar of Late Modern English* was effectively a synchronic study of what, to him, was present-day English. Poutsma describes his work as "a methodical description of the English Language as it presents itself in the printed documents of the last few generations" (Poutsma, 1928: viii). Sweet seems to have invented the now familiar tripartite division of the history of English when he proposed in a lecture to the Philological Society to "start with the three main divisions of *Old, Middle* and *Modern*, based mainly on the inflectional characteristics of each stage"

English, Later Modern (ca. 1700–1900)

J Beal, University of Sheffield, Sheffield, UK

Introduction

The recognition of Late Modern English as a separate period in the history of the English language is a fairly recent phenomenon. The first linguist to use the phrase appears to be Poutsma, but his (1914) *A grammar of Late Modern English* was effectively a synchronic study of what, to him, was present-day English. Poutsma describes his work as "a methodical description of the English Language as it presents itself in the printed documents of the last few generations" (Poutsma, 1928: viii). Sweet seems to have invented the now familiar tripartite division of the history of English when he proposed in a lecture to the Philological Society to "start with the three main divisions of *Old, Middle* and *Modern*, based mainly on the inflectional characteristics of each stage"

(Sweet, 1873–1874: 620). His definition of Modern English was the period of lost inflections, i.e., from the 16th century to Sweet's own lifetime. It was not until the early 20th century that a subdivision of Modern English was called for by Wyld:

> We should further distinguish Early Modern, from 1400 or so to the middle of the 16th century; and after that it is convenient to distinguish late 16th-century, 17th-century, and 18th-century English and we may consider present-day English to begin toward the end of the 18th century (Wyld, 1936: 27).

Wyld thus recognized a distinction between Early Modern English and the later history of the language, but does not see this later period as a coherent entity worthy of a single label. As I have pointed out elsewhere (Beal, 1999, 2004), the study of Late, or Later Modern English, as it is sometimes termed, has been the 'Cinderella' of English historical linguistics: serious study of this period did not begin until the end of the 20th century, perhaps because it was not until the millennium was in sight that the Late Modern period could be seen in historical perspective. This is the explanation provided by Charles Jones:

> There has always been a suggestion . . . especially among those scholars writing in the first half of the twentieth century, that phonological and syntactic change is only properly observable at a great distance and that somehow the eighteenth, and especially the nineteenth centuries, are 'too close' chronologically for any meaningful observations concerning language change to be made (Jones, 1989: 279).

Jones has been a pioneer in the study of Late Modern English, organizing the first conference dedicated to this period in 2001, the proceedings of which have appeared as Dossena and Jones (eds.) (2003). Görlach has produced separate volumes dedicated to 18th and 19th century English, respectively (Görlach, 1999, 2001), and Bailey (1996) likewise deals with the 19th century separately, leaving Beal (2004) as the first book to cover the whole of this period in a single volume. Although the latter defines 'later' Modern English as covering the period 1700–1945, I will deal here with the period (roughly) from 1700 to 1900, leaving the 20th century to the article **English in the Present Day (since ca. 1900)**.

External History

Although the division between the Early and Late Modern periods is not defined by a single cataclysmic external event such as the Norman Conquest, there are several factors contributing to the view that a date around 1700 marks the beginning of a new era. Historians generally describe the 'long' 18th century as beginning with the Restoration of the monarchy in England (1660) and ending with the fall of Napoleon (1815), while the 'long' 19th century stretches from the start of the French Revolution (1789) to the end of World War I (1918). These overlapping 'long' centuries together provide a good working definition of the Late Modern period in English. 'Restoration' is perhaps a misnomer for the accession of Charles II, since, far from occupying the throne by Divine Right, he had been invited to do so by Parliament. The so-called Glorious Revolution of 1688 and the Bill of Rights (1689) further reduced the powers of the monarch, bringing in the constitutional system that still exists in Britain.

1660 is also the year when the Royal Society was founded, ushering in the Age of Reason. Both Porter (2000) and Lass (1999) cite the publication of Newton's *Principia* (1687) as the beginning of the English Enlightenment. Scientific progress from throughout the Late Modern period stimulated lexical innovation as new inventions, processes, and whole disciplines required names. The emphasis on 'reason' in the 18th century also contributed to the climate of opinion, described by Leonard (1929) as the Doctrine of Correctness, in which grammatical 'rules' such as the proscription on negative concord ('two negatives make a positive') were rationalized on mathematical models. The scientific discoveries of the late 17th and early 18th centuries led to the technological innovations that drove the Industrial Revolution of the late 18th and 19th centuries. As Britain became an industrial nation, workers moved from the countryside to the newly expanding towns and cities, especially in the English North and Midlands. In cities such as Manchester, Leeds, and Birmingham, new urban dialects evolved as the demand for labor brought in workers from various parts of Britain and beyond.

Dialect contact, and an awareness of the differences between dialects of English, was made possible by advances in transport and communications during the Late Modern period. In the course of the 18th century, the Turnpike Trusts funded a substantial number of new roads, cutting the journey from York to London from three days to one, thus making leisure travel a more pleasant and practical proposition. Travelogues such as Defoe's *A tour thro' the whole island of Great Britain* (1724–1727), Johnson's *Journey to the Western Isles of Scotland* (1755) and Cobbett's *Rural rides* (1830) describe journeys by carriage undertaken for curiosity. The 'outlandish' dialects of Northumberland and Cornwall (the areas of England most remote from London) are as much objects of curiosity for Defoe as the landscape and customs of other areas. In the course of the 19th

century, the development of the railway made affordable leisure travel possible for the lower and middle classes, at least in urban areas. Communication was further facilitated by the introduction of the Penny Post in 1840 and the electric telegraph in 1837, while the invention of the phonograph in 1877 made it possible to hear the disembodied voices of speakers from distant places. All these developments had the effect of increasing dialect contact between speakers of different British dialects and, eventually, between speakers (and writers) of British and American English.

The Late Modern period also marks the beginning of the 'great divide' between British and American English. Although the first English-speaking colonies in what is now the United States were founded in the early 17th century, the development of American English as a national variety with its own prescribed norms was precipitated by the American Revolution (1775–1783). In 1789, Webster asserted that 'customs, habit and *language*, as well as government, should be national. America should have her *own*, distinct from all the world.' (Webster, 1789: 179). His *American dictionary of the English Language* (1828) provided norms for spelling which were deliberately differentiated from those of British English, as well as legitimizing Americanisms. With the loss of America, British colonial expansion diverted to Australia (1788) and, in the 19th century, to South Africa and New Zealand. The development of distinct national varieties of English in these countries was perhaps more a phenomenon of the 20th century, but the expansion of British interests both in these colonies and the nations of Africa and Asia absorbed by the British Empire, brought into English loan words from a wide variety of languages, as flora, fauna, topographic features, and customs hitherto unknown to speakers of English required names. This, along with the scientific discoveries and inventions referred to above, accounts for the increase in lexical innovation during the 19th century.

Within Britain, increased social mobility brought about by the commercial opportunities of the Industrial Revolution and the expansion of educational provision in the course of the Late Modern period led to the emergence of an ambitious and influential middle class. Such 'social climbers' created a market for the normative texts for which this era is famous: alongside the 'triumvirate' of Johnson (1755), Lowth (1762), and Walker (1791), many other dictionaries, grammars, and pronouncing dictionaries were published to help those aspiring to linguistic correctness. Whether such normative works had any effect on the language, or whether they simply described linguistic practices already in use among the educated, is still a matter of debate (see, for instance, Beal, 2003), but it is certainly the case that the codification of Standard (British) English is one of the defining features of the Late Modern period. The following sections provide a brief account of the major changes that took place in the Late Modern English Period, but it is to be understood that this refers only to Standard English in England. For discussion of the history of other varieties of English, see Beal (2004: 190–220) and Watts and Trudgill (2002).

Morphology and Syntax

Morphology

We have seen above that Sweet defined the Modern English period as a whole as the period of lost inflections. However, this definition refers largely to the Early Modern period, as the only inflection to be lost after 1700 is the second person singular-*st* ending. This in turn depends on the loss, from Standard English, of the distinction between second person singular *thou, thee, thy, thine* and the formerly plural *ye, you, your, yours*. The singular forms had become marked in the Early Modern period, and by 1700 "survived only in dialects, among Quakers, in literary styles, as a device of heightening . . . and in its present religious function" (Strang, 1970: 140). Although some 18th-century authors, notably Sheridan and Richardson, put *thou* forms into the mouths of upper-class males, this usage was not universally accepted. McKnight (1928, reprinted 1968: 335) cites Greenwood (1711) as stating "it is counted ungentile and rude to say, *Thou dost so and so*." Of course, the loss of *thee/ thou* pronouns and the *-st* verb inflection (along with *art, wert* forms of *be*) meant that Standard English no longer marked the distinction between second person singular and plural. In the early 18th century, the distinction was maintained, at least with *be*, by using *you was* for the singular and *you were* for the plural. However, Lowth condemned this as an "enormous solecism" (Lowth, 1762: 48), and *you was* disappeared from Standard English, though it is still common in dialects. By the end of the 19th century, a new plural form *yous* was being used in Irish, American, and Australian English (Wright, 1898–1905), and this form has spread throughout Britain in the late 20th century (Cheshire *et al.*, 1993).

Syntax: Regulation of Early Modern Variants

Syntactic changes in the Late Modern period can be divided into two types: those that represent the final stages of processes begun in the Early Modern period, and those that are innovations of the 18th and 19th

centuries. The former type involve the regulation of variants, a process to some extent helped along by the prescriptive grammarians of the Late Modern Period. Changes in the auxiliary system led, in the Early Modern period, to variation between positive declarative causes with and without *do*. While the 16th-century grammarian Palsgrave was able to state: "*I do* is a verb moche comenly used in our tonge to be put before other verbs, as it is all one to say 'I do speake', and such lyke, and 'I speake'" (Palsgrave, 1530: 523), Johnson condemned this usage as "a vitious mode of speech" (Johnson, 1755: Sig. B2v). Ellegård (1953: 162) provides a graph demonstrating the decline of this construction through the Early Modern period, reaching close to zero by 1700. However, Tieken (1987) found that, in a corpus of 18th-century prose (948,700 words), the construction was still used, but it was rare, and 13 out of the 14 examples she found occurred before 1760. In poetry, the use of *do* before another verb persisted into the 19th century, presumably because the semantically empty auxiliary here provided an extra syllable when needed, and allows the citation form of the verb to be placed at the end of a line, thus facilitating rhymes. An example from Wordsworth (1827) is:

> The hapless creature which did dwell
> Erewhile within the dancing shell.
> (*The blind highland boy* 193–194)

However, it is certainly the case that this usage was extremely marked after the mid–18th century, at least in Standard English. Another, related, area in which Early Modern variants persist into the 18th century is negation: Ellegård (1953: 162) shows the use of *do* in negative declaratives in his corpus rising to 80% by 1700, with the steepest rise in this usage coming in the second half of the 17th century. Tieken (1987) found that an average of 76% of the negative declaratives in her 18th-century corpus involved the use of *do*, and that the decline of the *do*-less negative was gradual throughout the 18th century. She also found that the *do* + *not* + infinitive construction was more frequent in the usage of more educated authors, but that the *do*-less form was most frequent with the verbs *know* and *doubt*.

Another area in which regulation took place during the Late Modern period is relativization. The so-called *wh*-relatives *who, whom, whose*, and *which* had been introduced in the Early Modern period, but the options of using *that* with both human and nonhuman antecedents, and of using a zero, or contact relative in both subject and object positions, were still available. The 18th century saw grammarians expressing a preference for *who/ whom/ whose* with human antecedents and *which* with nonhuman antecedents, and condemning the zero relative. However, although Visser (1963–1973: 540) states that "a remarkable decline in the currency of the zero-construction becomes perceptible" in the 18th and 19th centuries and notes that Johnson called this "a colloquial barbarism," Raybould (1998) notes that Johnson uses this construction even in the nominative. It would appear that 18th-century authors saw this construction as informal or colloquial rather than strictly ungrammatical. The only substantive changes in relativization in Late Modern English are the restriction of *which* to use with inanimate antecedents, and the restriction of zero-relatives in the nominative to colloquial usage, and to existential constructions such as *there's a man out here wants to see you*.

Syntax: Innovations of the Late Modern Period

Perhaps the most fully researched feature of Late Modern syntax is what has been called the '*be* + *-ing*' construction, the 'progressive' and the 'expanded form,' as in *She is reading a book*. Although this construction had been used before 1700, its use in Early Modern English was optional in contexts where today it would be required. Thus in *Hamlet* II. 2. 190, Polonius asks Hamlet "What do you read my Lord?" Today this would be interpreted as an inquiry into Hamlet's reading habits, but Polonius was referring to the book that Hamlet had in his hands at the time. Today, the required construction in this pragmatic context would be *What are you reading, my Lord?*

Several studies (Dennis, 1940; Strang, 1982; Arnaud, 1983) have noted the increase in usage of the *be* + *-ing* construction throughout the Late Modern period, both in terms of the sheer numbers of such constructions, and the types of clause in which it can occur. Strang notes that before 1750 the construction is used mainly in subordinate clauses, but that, from the second half of the 18th century, the rise in the use of *be* + *-ing* constructions is proportionately greater in nonsubordinate clauses. Thus, the construction becomes fully grammaticalized in the course of the Late Modern period. Likewise, from the second half of the 18th century, there is a rise in the use of *be* + *-ing* with stative verbs such as *love, wish*, etc., with verbs denoting instant actions such as *explode, fall*, etc., and with nominal and adjectival complements (e.g., *You're being a fool/foolish*). The extension of *be* + *-ing* to the passive is likewise an innovation of the Late Modern period. As late as 1870, this construction was still being condemned by grammarians such as Marsh, who described it as "at war with the genius of the English Language" (Marsh, 1860: 465). The preferred form, for Marsh, was *the house is*

building. However, this had in turn been condemned by Johnson (1755) as an unacceptable innovation:

> The grammar is now printing, brass is forging … in my opinion a vitious expression probably corrupted from a phrase more pure but now somewhat obsolete: a printing, a forging.

While examples of the *a-printing* type are found in early 18th-century literature, by the 19th century they are being used (*sic.*) to represent nonstandard speech. In Richardson's *Pamela* (1740), the sentence "this girl is always a-scribbling" is given to an educated, upper-class man, but in George Eliot's *The mill on the floss* (1860), the same construction conveys uneducated, lower-class usage: "I hope, sir, you're not a-thinking as I bear you any ill-will … I'm not a-defending him." The first examples of the passive with *be* + *-ing* are found in late 18th-century letters, such as the following, cited in Denison (1998: 152):

> I have received the speech and address of the House of Lords; probably, that of the House of Commons was being debated when the post went out. (1772, Harris, *Letters*)

Letters are, of course, the most informal genre of writing: we have already seen that Marsh was reluctant to accept this construction a century later, and, even in the early 20th century Curme and Kurath seem to begrudge it:

> From 1825 on … the form with *being* + perfect participle began to lead all others in this competition, so that in spite of considerable opposition the clumsy *is being built* became more common than *is building* in the usual passive meaning, i.e. where it was desired to represent a person or thing as affected by an agent working under resistance vigorously and consciously to a definite end: 'The house *is being built*', 'My auto *is being repaired*' (Curme and Kurath, 1931: 444)

The extension of the use of the *be* + *-ing* construction to longer verb phrases involving perfective and modal verbs took longer. Marsh constructs such sentences as artificial examples of what he sees as the ludicrous consequences of allowing the passive with *be* + *-ing*:

> They must say therefore … the great Victoria bridge *has been being built* more than two years; when I reach London, the ship Leviathan *will be being* built; if my orders had been followed, the coat *would have been being made* yesterday; if the house had then *been being built*, the mortar would *have been being* mixed (Marsh, 1860: 654).

However, Marsh's ridicule was in vain, for, by the early 20th century, such constructions were in use: they were rare then as now, simply because the pragmatic circumstances in which they might be used are likewise rare. An early example is from Galsworthy: "She doesn't trust us: I shall always be being pushed away from him by her" (Galsworthy, 1915, *Freelands*, cited in Denison, 1998: 158).

The extension of the *be* + *-ing* form to the passive and to other paradigms is perhaps the most significant syntactic innovation of the Late Modern period. Other changes tend to involve, as Denison notes, "a given construction occurring throughout the period and either becoming more or less common generally or in particular registers" (Dension, 1998: 93). The role of prescriptive grammarians in relegating constructions such as the double negative to nonstandard usage in this period is a matter of debate. Greenwood's statement that "two *Negatives* or two *Adverbs of Denying,* do in *English* affirm" (Greenwood, 1711: 160) is often cited as an example of mathematical logic inappropriately applied to language. Yet Tieken (1982) and Austin (1984) note that, in the 18th century, multiple negation occurs in informal and lower-class writing, and in the portrayal of such usage by playwrights. Whether the grammarians created the stigma or merely reflected the sociolinguistic situation of their day is as difficult a question as that of prioritizing the chicken and the egg. What is certain is that multiple negation disappears from formal Standard English in the course of the Late Modern Period. Other constructions condemned by grammarians, such as preposition stranding and the split infinitive remain shibboleths to this day, and are perhaps more common in informal Standard English, but have by no means disappeared. In fact, Lowth, who is often cited as proscribing preposition stranding, merely states that this "is an idiom, **which our language is strongly inclined to**" and that this "prevails in common custom, and suits very well with the more familiar style in writing; but the placing of the Preposition before the Relative is more graceful … and agrees much better with the solemn and elevated style" (Lowth, 1762: 167–168, my emphasis). As Tieken (2000) points out, Lowth's use of the very construction he is supposedly condemning, is intended as a joke, and, far from proscribing preposition stranding, Lowth states that it is perfectly suitable for informal writing and, indeed, uses it in his own letters. His statement appears to be a description of 18th-century usage. The split infinitive was never mentioned by Lowth or any other 18th-century grammarian: it is first mentioned in 1834 in the *New England Magazine*, where it is represented as "not unfrequent among uneducated persons" (Lowth, 1834: 469, cited in Bailey, 1996: 248). If educated persons avoid the split infinitive in formal writing

today, this is largely because it has become such a shibboleth.

Phonology

The phonology of Late Modern English has, until very recently, had much less scholarly attention paid to it than that of earlier periods. This is probably because, as MacMahon suggests "superficially, the period under consideration might appear to contain little of phonetic and phonological interest, compared with, for example, earlier changes such as the transition from Old to Middle English, and the Great Vowel Shift" (MacMahon, 1998: 373). It is in the Late Modern period that, as Holmberg so neatly puts it, "the snob value of a good pronunciation began to be recognised" (Holmberg, 1964: 20), and elocutionists such as Thomas Sheridan and John Walker made good livings from providing lectures and pronouncing dictionaries (Sheridan, 1780; Walker, 1791) to the upwardly mobile. This is also the period in which Received Pronunciation emerged as the sociolect of the public-school-educated aristocracy and upper-middle class, eventually to become the reference variety of British English. When we discuss changes in English phonology and phonetics in this period, it has to be understood that we are comparing the reference varieties of the 18th and 19th centuries, as set out, for instance, in successive editions of Walker's *Critical pronouncing dictionary* from 1791 to 1904, with 20th-century RP as defined in those of Daniel Jones (first edition 1917). Other varieties of present-day English tend to retain variants 'left behind' by Late Modern English sound changes such that a passage transcribed according to Walker (1791) would sound regional and/or slightly archaic rather than obsolete or outlandish to a 21st-century British ear (see Beal, 2004: 134 for such a transcription). Although elocutionists such as Walker and Sheridan were undoubtedly normative, their detailed descriptions of sounds and transcriptions of every word in their dictionaries provide a great deal of evidence for the prestigious pronunciation of the period. A more detailed account can be found in Beal (1999 and 2004: 125–167): here, I will briefly describe the main changes in the pronunciation of received English between 1700 and 1900.

Consonants

Perhaps the most striking difference between the pronunciation set out in Walker (1791) and present-day RP is that the former is rhotic, with orthographic <r> pronounced in all positions. The loss of rhoticity is attested by Walker, who is one of the first sources of evidence for this change, but he considers this to be a marker of lower-class London usage:

> In England, and particularly in London, the r in *lard, bard, card, regard*, is pronounced so much in the throat, as to be little more than the middle or Italian a lengthened into *baa, baad, caad, regaad* (Walker, 1791: 50).

He goes on to describe the Irish pronunciation of /r/ as too harsh, but to say that the pronunciation at the beginning of a word should be more 'forcible' than at the end, so that '*Rome, river, rage*, may have the r as forcible as in Ireland, but *bar, bard, card, hard*, etc. must have it nearly as soft as in London (Walker, 1791: 50). This suggests that, even in the pronunciation recommended by Walker, /r/ was considerably weakened in final and preconsonantal positions. However, as Mugglestone (1995: 98–103) demonstrates, 'dropping' of <r> continued to be overtly stigmatized until the late 19th century. Loss of rhoticity in British, or, rather, English English, appears to have been a 'change from below,' first noticed in lower-class London English of the late 18th century and eventually to find its way into RP. In the 20th century, rhoticity became recessive even in regional dialects of England, remaining as a marker mainly of southwestern and some Lancashire dialects.

The other main consonantal changes in Late Modern English are not so much changes in the system, or even the distribution of phonemes, as the regulation of variants. Two of the greatest shibboleths of nonstandard pronunciation in the 20th and 21st centuries are popularly known as 'dropping' of <h> and <g>. In the latter case, the term 'dropping' is not at all accurate, since the stigmatized variant is /n/ as opposed to /ŋ/ in, for example, *hunting, shooting*, and *fishing*. In both cases, the stigmatized variants had been attested at least from the Early Modern period, but are not labeled as 'vulgar' or 'incorrect' before the 18th century. Sheridan was the first to comment on 'h-dropping':

> There is one defect which more generally prevails in the counties than any other, and indeed is gaining ground among the politer part of the world, I mean the omission of the aspirate in many words by some, and in most by others (Sheridan, 1762: 34).

Walker lists among the 'faults of the Cockneys' that of "not sounding *h* where it ought to be sounded, and inversely" "(Walker, 1791: xii–xiii). For both Walker and Sheridan, the dropping of /h/ from the /hw/ of *which, what*, etc. is as much a 'fault' as the omission of initial /h/ in *house*, etc. While h-dropping remains highly stigmatized in all but a handful of words of French origin (*hour, honour, herb* and derivatives), the initial /hw/ is now marked in RP as very

conservative. For a full account of the extent to which h-dropping became a shibboleth in the course of the Late Modern period, see Mugglestone (1995: 107–150). The stigmatization of the alveolar pronunciation of <ing> was equally strong by the late 20th century, but here the story is more complex, involving social stratification. Walker was aware of the distinction between /n/ and /ŋ/ and provides evidence that the use of /ɪn/ for the *-ing* morpheme was condemned by some teachers, but he states that "our best speakers do not invariably pronounce the participle *ing*, so as to rhyme with *sing, king* and *wing*" (Walker, 1791: lxxxviii). The alveolar pronunciation was a marker both of lower-class and upper-class usage throughout the Late Modern period. By the early 20th century, the upper-class use of the alveolar was becoming a target of humor, but it can still be heard in the speech of very elderly, very conservative RP speakers.

Vowels

Such vowel changes as occurred in the Late Modern period largely involve the continuation of processes begun in the 16th and 17th centuries. In all cases, the earlier variants are still found in English regional accents, with many of the innovations still confined to RP and southern varieties. One of the clearest and most persistent markers of the 'north–south divide' in English accents, the presence or absence of /ʌ/ in *blood, cup, put*, etc. had already been established by the mid-18th century, as Walker points out:

> If the short sound of the letter **u** in *trunk, sunk* etc., differ from the sound of this letter in the northern parts of England, where they sound it like the **u** in *bull* … it necessarily follows that every word where this letter occurs must by these provincials be mispronounced' (Walker, 1791: xiii).

What is new here is not the southern /ʌ/ so much as the attitude that the northerners' lack of this phoneme marks them out as provincial. That other marker of the north–south divide, the pronunciation of the vowel in *bath, laugh, grass*, etc., has a more complex history. Evidence of lengthening of /æ/ in certain environments, mainly before voiceless fricatives, preconsonantal (but not final) /r/, and /n/ followed by another consonant, as in *dance*, etc. occurs in the late 17th century, but, throughout the 18th and 19th centuries, the pronunciation with /ɑː/ was not universally accepted. Walker tells us that although 'Italian *a*' had previously been heard in words such as *glass, fast* "this pronunciation seems to have been for some years advancing to the short sound of this letter, as heard in *hand, land, grand* etc. and pronouncing the *a* in *after, answer, basket, plant, mast*, etc. as long as in *half, calf* etc. borders very closely on vulgarity" (Walker, 1791: 10). This change seems to have begun as a lengthened [æː] in the 17th century, and not to have become stigmatized until the lengthened vowel was retracted to [ɑː]. The latter pronunciation is described as 'drawling' throughout the 19th century, and there is evidence of a pronunciation with [æ] or even [ɛ] by young ladies wanting to avoid the 'vulgar' [ɑː]. Those who wished their pronunciation to be beyond reproach had to avoid both the 'drawling' [ɑː] and the 'mincing' [æ] at least until the beginning of the 20th century, when Daniel Jones's use of cardinal **ɑ** seems to have established this as the RP pronunciation. The lengthening of short *o* to /ɔː/ in *off, cloth, cross*, etc., likewise began in the late 17th century and was considered 'vulgar' through most of the Late Modern period. Walker explicitly draws a parallel between the two vowels:

> What was observed of the *a*, when followed by a liquid and a mute, may be observed of the *o* with equal justness. This letter, like *a*, has a tendency to lengthen when followed by a liquid and another consonant, or by *s, ss* or *s* and a mute. But this length of *o*, in this situation, seems every day growing more and more vulgar; and, as it would be gross, to a degree, to sound the *a* in *castle*, *mask* and *plant*, like the *a* in *palm, psalm,* &c. so it would be equally exceptionable to pronounce the *o* in *moss, dross* and *frost*, as if written *mawse, drawse,* and *frawst*. (Walker, 1791: xx)

As Mugglestone (1995: 231) points out, both [ɑː] in *bath*, etc., and [ɔː] in *off*, etc., were condemned as 'vulgar' throughout the 19th century, most probably because of their association with Cockney, and both became acceptable in 20th-century RP. However, while the former remains in present-day RP and southern accents of England, [ɔː] in *off* is now a stereotype of very conservative, very upper-class RP, such as that of older members of the Royal Family.

The other vowel changes to be considered here could be regarded as the tail-end of the Great Vowel Shift. In words such as *face* and *goat*, the ME vowels had been raised to /eː/, /oː/, respectively, and these are the pronunciations described by Walker, who writes of the 'long, slender' sound of <a> and the 'long, open' sound of <o>, respectively. While the exact quality of the vowels described by Walker is open to debate (MacMahon, 1998: 450; Beal, 2004: 136–138), the pronunciations described are monophthongal. However, the first evidence for diphthongal pronunciations of both these vowels comes very soon after Walker's first edition: MacMahon (1998: 459) points out that the first evidence for diphthongization of /oː/ comes from the Scottish orthoepist William

Smith in 1795 and it is generally accepted that the first attestation of a diphthongal pronunciation of /eː/ comes from Batchelor (1809). In both cases, the diphthongal pronunciations are widely accepted in the 19th century, and are still found in RP and many other accents of present-day English.

Lexical Innovation

Given the external factors referred to above, we would expect the Late Modern period to be a time of lexical expansion, as all the new inventions and discoveries of the scientific age would require names, and English speakers encountered a wide variety of languages as a result of trade, exploration, and colonization. **Figure 1** is based on information provided by the *Chronological English dictionary* (Finkenstaedt *et al.*, 1970), which, in turn, took its data from the *Shorter Oxford English dictionary*. Most recent accounts of lexical innovation in English, such as Bailey (1996) and Görlach (1999, 2000), take their information from this source, even though it has limitations. **Figure 1** shows a distinct downturn in lexical innovation in the mid-18th century, an increase in the 19th century, reaching a peak in the mid-19th century, and a tailing-off toward the 20th century. The apparent decline at the end of the 19th century can be dismissed as the information ultimately comes from the first edition of the *Oxford English dictionary*, which was being produced at the end of the 19th century and therefore did not tend to include innovations from this period. The *OED online* provides a more accurate picture: for instance, a search for the year 1890 under 'first citations' provides 1235 entries. The apparent trough in the 18th century can partly be explained by the relative neglect of 18th-century sources on the part of the original *OED* compilers, but it is also true that there was a tendency to resist innovation in this period. Authors such as Swift and Addison satirized the 'affectation' of slang words such as *mob* and *bamboozle* and the importation of French military terms such as *corps* and *c(h)arte blanche*. Objections to loanwords from French were voiced at various points in the 18th and early 19th centuries, when war between the two nations brought speakers of French and English into contact, and news of France's superior military engineering into the English papers. Several reviews in 18th-century periodicals comment adversely on the influx of French military terminology, but even in times of peace, the excessive use of French words is condemned as an affectation. In 1771, the *Monthly Review* criticizes those who use *rôle* for *part* or *penchant* instead of *the passion of love*, stating that "the offended ear of the unfrenchified reader sickens at the sound" of these words. Of course, both these words are now accepted in English, but, like many French loans of the Later Modern period, they have not been fully anglicized. Apart from French, the other major sources of loanwords in the 18th century were Latin and, to a lesser extent, Greek. Publications such as Chambers *Cyclopaedia* brought information on new scientific classifications, discoveries, and inventions to a wide readership, introducing words coined from classical roots. Examples from 1753 are *aeronautics, azalea*, and *caldarium* from Latin, and *aetiological, eczema*, and *splenitis* from Greek: all of these were first cited in the 1753 supplement to Chambers *Cyclopedia*. The number and the proportion of new words formed from classical roots was to increase substantially in the 19th century: figures from *CED* for 1835 show more than two-thirds of the words first cited in that year having Latin or Greek etymologies (Beal, 2004: 25). Some 19th-century authors objected to what they saw as an excessive dependency on these sources. Richard Grant White complained:

> In no way is our language more wronged than by a weak readiness with which many of those who, having neither a hearty love nor a ready mastery of it, or lacking both, fly readily to the Latin tongue or to the Greek for help in naming a new thought or thing or the partial concealment of an old one (1872, 22, cited in Bailey 1996: 141–142).

Despite such complaints, many of the scientific discoveries and inventions of the 19th century were given names coined from classical roots: examples

Figure 1 Numbers of first citations in the *Shorter Oxford English Dictionary* by decade 1661–1900.

from 1835 are *bifurcate, capilliform*, and *locomotory* from Latin and *creosote, phonograph*, and *silo* from Greek. The scientific discoveries of this century also led to a growth in the number of eponyms, as inventors or discoverers claimed a stake in posterity by having a new process or mineral named after them. The new science of geology provided many new words for minerals named after the geologist who first found them or the place they were found: examples first cited in 1835 include *bromlite, lanarkite, leadhillite, proustite, smithsonite, stromeyerite, troostite, uralite*, and *voltzite*. These are the major sources of lexical innovation in the 19th century, but what is also evident is that, as the Late Modern period progresses, words are imported into English from a wider variety of languages as exploration and colonization brought terms for the flora, fauna, and customs of the Americas, Asia, Africa and, last of all, Australasia. In 1835, for instance, the words *kiwi, rata*, and *tui* are first cited, all from Maori.

The English of the period between the Norman Conquest of 1066 A.D. and the arrival of printing in England in 1476 is generally referred to as Middle English, as opposed to Old English (before 1066) and New or Modern English (after c. 1500). This terminology was established by the late-19th-century scholars Henry Sweet and Julius Zupitza. The dates are, of course, only useful signposts because the transitions between the three periods were gradual.

External History

William of Normandy's victory over the Anglo-Saxons was followed relatively swiftly by the imposition of Norman political and cultural hegemony throughout the kingdom. By William's death in 1087, the first two classes (estates) of medieval society, the clergy and nobility, were dominated by Normans.

This major change in England's social structure had a profound effect on the status of the English language, which had hitherto occupied a position unparalleled among the western European vernaculars. When the Normans arrived, they found a sophisticated society that had developed a distinctive vernacular culture. Spoken Old English consisted of a range of different varieties, strongly affected – especially in the north and east of England – by the Norse dialects of Viking settlers. In the written mode, however, one Old English dialect, the Late West Saxon in southwest England, had achieved the prestige associated with standard languages (*see* **Standardization**) and was copied in various scriptoria, largely monastic, outside its area of origin. The Norman Conquest ended the prestige of Late West Saxon and, although texts continued to be copied in this standardized language for some time after 1066, dialectal variation and linguistic changes, hitherto not evidenced in written English, began to spread from the spoken to the written mode. The resulting language was Middle English, the earliest surviving example of which is probably the Final Continuation of the *Peterborough Chronicle* (see Clark, 1970).

Two languages replaced Late West Saxon in prestige: Latin and Norman French. The Conquest coincided with a revival of Latin learning in western Europe, and the Channel State of England and Normandy resulting from William's victory aided the transmission of this culture to Britain. Latin became the language of official record in England during the 12th and early 13th centuries, used for the *Domesday Book* (1086) and the Magna Carta (1215); it was also the literary language used by important 12th-century writers working in England, such as Geoffrey de Vinsauf, Alexander Neckham, and John of Salisbury.

Norman French, although the mother tongue of the invading elite, could not at first compete with Latin in all its functions. However, as Clanchy (1979: 168) pointed out, "contact with England, with its long tradition of non-Latin writing, may have helped to develop French as a written language"; and, from the 13th century onward, as Norman French developed

The English of the period between the Norman Conquest of 1066 A.D. and the arrival of printing in England in 1476 is generally referred to as Middle English, as opposed to Old English (before 1066) and New or Modern English (after c. 1500). This terminology was established by the late-19th-century scholars Henry Sweet and Julius Zupitza. The dates are, of course, only useful signposts because the transitions between the three periods were gradual.

External History

William of Normandy's victory over the Anglo-Saxons was followed relatively swiftly by the imposition of Norman political and cultural hegemony throughout the kingdom. By William's death in 1087, the first two classes (estates) of medieval society, the clergy and nobility, were dominated by Normans.

This major change in England's social structure had a profound effect on the status of the English language, which had hitherto occupied a position unparalleled among the western European vernaculars. When the Normans arrived, they found a sophisticated society that had developed a distinctive vernacular culture. Spoken Old English consisted of a range of different varieties, strongly affected – especially in the north and east of England – by the Norse dialects of Viking settlers. In the written mode, however, one Old English dialect, the Late West Saxon in southwest England, had achieved the prestige associated with standard languages (*see* **Standardization**) and was copied in various scriptoria, largely monastic, outside its area of origin. The Norman Conquest ended the prestige of Late West Saxon and, although texts continued to be copied in this standardized language for some time after 1066, dialectal variation and linguistic changes, hitherto not evidenced in written English, began to spread from the spoken to the written mode. The resulting language was Middle English, the earliest surviving example of which is probably the Final Continuation of the *Peterborough Chronicle* (see Clark, 1970).

Two languages replaced Late West Saxon in prestige: Latin and Norman French. The Conquest coincided with a revival of Latin learning in western Europe, and the Channel State of England and Normandy resulting from William's victory aided the transmission of this culture to Britain. Latin became the language of official record in England during the 12th and early 13th centuries, used for the *Domesday Book* (1086) and the Magna Carta (1215); it was also the literary language used by important 12th-century writers working in England, such as Geoffrey de Vinsauf, Alexander Neckham, and John of Salisbury.

Norman French, although the mother tongue of the invading elite, could not at first compete with Latin in all its functions. However, as Clanchy (1979: 168) pointed out, "contact with England, with its long tradition of non-Latin writing, may have helped to develop French as a written language"; and, from the 13th century onward, as Norman French developed

in England into what modern scholars call Anglo-Norman, it began to be used for both official and literary purposes.

Throughout this period, English remained the primary language of the majority of the population of England, which peaked at just over 6 million in the middle of the 14th century. There is good evidence that the Norman aristocracy themselves had begun to speak English by the beginning of the 12th century, although French remained a necessary accomplishment for cultivated people; the change was encouraged by the loss of Normandy in 1204. English became increasingly widely used in the written mode as the Middle Ages progressed. However, its functions were parochial; it was used for local audiences and in the equivalent of primary education. The national functions of written language, until the very end of the period, were carried out by Latin and French; there was therefore no need of a national standard English. As a result, written English for much of the Middle English period manifested a high degree of variation of the kind now more generally associated with speech. There are, for instance, 143 distinct spellings for the item *such* recorded in the authoritative *Linguistic atlas of late mediaeval English* (McIntosh *et al.*, 1986), ranging from *schch* recorded in Norfolk to such forms as *swich*, *seche*, and *soche* to Kentish *zuyche* and Northern *swilk* and *slik*. It was only in the 15th century, with the rise of London English as a prestigious written language associated with the power and functions of the capital city, that a new standard written English emerged. Even then, extensive written variation remained into the 16th century, at which point the early printers began to provide authoritative norms for private use.

Internal History

Increased vernacular literacy from the 13th century onward means that, compared with Old English, a great deal of Middle English writing in contemporary manuscripts has survived. This material forms the primary evidence for Middle English.

Graphology

Given the variety of written Middle English, it is unsurprising that handwriting styles differed diachronically and diatopically and even in the work of single scribes. In general, the Old English insular script was replaced by continental styles; usages hitherto restricted to Latin texts began to be adopted when writing English. Cursive handwriting developed as a practical response to increasing literacy in both Latin and the vernaculars.

The Middle English alphabet was almost identical with that of present-day English. The Old English letters <æ> (ash), <ð> (edh), and <ƿ> (wynn) disappeared early in the Middle English period, being replaced by <a, e>, <th, þ>, and <w>, respectively. Old English runic <þ> (thorn) was retained alongside its ultimate replacement, <th>, for some time, although commonly realized as <y>, especially in northern varieties; when printing arrived, <þ> largely disappeared, but was retained (written <y>) in a few contexts where ambiguity did not arise, for example, <ye> 'the.' A modified form of the Old English insular g, <ȝ> (yogh), was retained by many scribes, commonly to represent [x, j]; the French habit of using <ȝ> to realize [z] was also adopted by many Middle English scribes, in addition to <z>, which was adopted from Latin usage. <g>, used in Anglo-Saxon times for copying Latin, was adopted to represent [g]. <c, k, q> developed their present-day usage during this period as a result of the adoption into English of practices used for writing French. <h> was used as a diacritic to indicate a modification of the letter it followed: hence, the development of <sh> (earlier <sch>) for Old English <sc>, <gh> for <ȝ> and <wh> for Old English <hw>. The letters <u, v> were used interchangeably to represent both vowel and consonant, with <v> generally being used initially and <u> elsewhere.

In Old English, <y> had represented [y], but that vowel was unrounded in many late Old English dialects, merging with Old English <i> [i] (In western dialects, the rounding was retained, but the vowel seems to have retracted to merge with <u> [u].) <y> then came to be used interchangeably with <i>, especially in environments where contemporary handwriting could be confusing (e.g., before or after <m, n, u>). <o> was used for <u> in similar circumstances.

The combinations <ou, ow> were adopted from French usage in place of <u> in words such as *how* and *brown* (cf. Old English *hu*, *brun*). Toward the end of the period, southern varieties frequently indicated vowel length by doubling the letters representing them (e.g., *good*, *feed*); however, in northern and Scottish varieties, long vowels were often indicated by the addition of <i> (e.g., *guid* 'good'). As inflexional-*e* fell out of use at the end of the period (see the section on Noun Phrases), it too became available as a diacritic mark to indicate a long vowel, as in *life* (cf. Old English *lif*).

Phonology

Knowledge of Middle English phonology derives from the analysis of rhyming verse, reconstruction

from later and earlier states of the language, and the interpretation of orthography. There is no thorough contemporary account of Middle English pronunciation comparable to the Old Icelandic *First grammatical treatise* (*see* **First Grammatical Treatise**), although there were scribes whose orthographic practices demonstrate considerable sophistication in handling the complexities of sound-symbol mapping (e.g., Orm, the author and scribe of *The ormulum*, c. 1200). The inventory of phonemes in Middle English varied diatopically and diachronically, so the following account is very general.

Consonants The phonemic consonants in Middle English were /p, b, t, d, k, g, tʃ, dʒ, f, v, θ, ð, s, z, ʃ, h, m, n, l, r, w, j/. The major structural difference between Old and Middle English was in the fricatives; voiced and voiceless fricatives were allophones in Old English, but were phonemicized in the Middle English period.

Vowels The Old English distinction between long and short stressed vowels remained important, but ceased to be phonemic as the Middle English period progressed; there is indirect evidence that the short vowels tended to have more open pronunciations than their long equivalents from the beginning of the 13th century onward. By the beginning of the 15th century, London English seems to have had the following inventory: /i, ɪ, e, ɛ, ɛː, aː, a, ɔ, ɔː, o, u, ʊ/; /i, e, o, u/ were long vowels where length had ceased to be phonemic. Quantitative changes, some already under way in the late Old English period, meant that short vowels tended to appear in closed syllables, whereas long vowels tended to appear in stressed open syllables; thus, contrastive distribution was lost.

The major difference between Old and Middle English vocalism was in diphthongs; the Old English diphthongs monophthongized, and new diphthongs arose from vocalizations of Old English [w, j, h]. French loanwords supplied the inventory with two new diphthongs, /ʊɪ, ɔɪ/.

In unstressed vowels, the Old English qualitative distinctions were already becoming obscured by the late Anglo-Saxon period. This process continued in Middle English; /ə/ was the most common vowel, although /ɪ/ spread from the north, and /ʊ/ (indicated by spellings such as <-us, -ud>) seems to have been characteristic of the west.

Grammar

Inflexion In Middle English, inflexions are not as functionally important as they were in Old English. Many roles played by inflexions in Old English were taken over by prepositions and a more fixed word order (see section on Word Order). There were, of course, dialectal differences. In general, innovations in morphology spread from the north of England to the south, so features found in late Northumbrian Old English (e.g., the 10th-century *Lindisfarne gospels gloss*) first appear in the south in Middle English texts.

Noun Phrase The masculine/feminine/neuter grammatical gender system of Old English disappeared in the Middle English period. Although inflexional distinctions remained in the personal pronouns of Middle English, these were assigned according to natural gender. This pattern was already becoming established in late Old English, when *wif* 'woman,' a neuter noun, was occasionally referred to by the pronoun *heo* 'she.' The case system had already been subject to syncretism in pre-Old English (as in all Germanic languages); it was during the Middle English period that it largely disappeared. Only inflexional markers of plurality and possession remained. Modifiers such as determiners and adjectives ceased to be marked for agreement with their head words.

In place of the four major and four minor noun declensions of Old English, Middle English had in general the modern pattern, that is, the simple addition of *-(e)s* to mark plurality or possession, although there were rather more relicts of the *mice/children*-type than there are in present-day English. The forms in *-s* derive from the Old English strong masculine paradigm.

Traces of the old adjectival strong/weak (indefinite/definite) distinction lasted until the late 14th century in southern England, indicated by the use of *-e* in some paradigms; thus the poet Geoffrey Chaucer (d. 1400) distinguished *the olde man* and *the man is old*. However, the system had died out everywhere by the beginning of the 15th century, and *-e* was subsequently used as a diacritic of length (see section on Graphology).

The Old English system of inflexionally differentiated determiners collapsed, and the present-day system (*the/this/that/these/those*) gradually emerged. An indefinite article *a(n)* appeared, derived from Old English *an* 'one.' Perhaps the most radical changes took place in the pronominals; the Old English dual pronouns disappeared, and a number of other forms (e.g., Old English *hie* 'they,' *heo* 'she'), which had ceased to be distinctive because of sound changes, were replaced by variants that were available in the lexicon through contact with Old Norse.

Verb Phrase The strong/weak/irregular paradigms of Old English remained, with numerous analogical reassignments. Verb inflexions, although reduced and reorganized, were retained to mark agreement between subject and predicator.

Complex verb phrases arose in place of some Old English simple verb phrases. Old English distinguished between *bundon* 'bound' (preterite plural indicative) and *bunden* 'may have bound' (preterite plural subjunctive); the obscuration of the inflexional distinction led to the replacement of the formal subjunctive by complex verb phrases with *may* and *might* (Old English *mæg*, *mihte*, etc., 'can, could'). *Shall* and *will* were increasingly used as auxiliary verbs indicating future time rather than as lexical verbs signaling obligation and volition, respectively. Toward the end of the Middle English period, a complex verb phrase with *do* emerged in affirmative declarative constructions (e.g., *she did eat*, *it doth illuminate*); this construction has not survived into present-day use.

Other characteristic Middle English innovations are the development of phrasal verbs, such as *put up* and *stand by*, and an extension of the use of impersonal verbs, such as *me thinketh* 'it seems to me.' The latter usage has disappeared from present-day use, but the former construction is still common, especially in informal styles.

Word Order In word order, there is a noticeable extension in Middle English of the subject-verb-object sequence from affirmative main clauses not beginning with an adverbial to main clauses beginning with an adverbial and to subordinate clauses, where the Old English orderings were prototypically adverbial-verb-subject-object and subject-object-verb, respectively (as in present-day German).

Lexicon

There are three main sources of loan words into English during this period: Norse, Latin, and French. (For useful lists, see Serjeantson, 1935.)

Norse Loans Many Norse words were actually taken into English in the late Anglo-Saxon period, but in general they are hidden by the standardized written mode. Most Norse loans express very common concepts (e.g., *bag, bull, egg, root, ugly, wing*), and it is notable that Norse has supplied such basic features as the third-person plural pronouns *they, their*, and *them* (cf. Old English *hie, hiera, him*).

Latin Loans A number of Latin words came directly into English during the Middle English period, largely as learned words carried over in the translation of Latin texts (e.g., *omnipotent* and *testament*). However, the great wave of Latin borrowings into English took place from the 15th century onward, with the rise of humanism, and this is therefore a feature of Early Modern English.

French Loans Up to the 13th century, recorded borrowings from French into English are few and were generally restricted to the registers of government (e.g., *justice, obedience, mastery, prison, service*). From the beginning of the 13th century to the end of the Middle English period, however, French words entered the English lexicon in large numbers. As contact with Normandy was lost, Central French, not Anglo-Norman, became the main source of these words. The range of domains covered by these words is vast (see Serjeantson, 1935: 12–156). This surge was socially driven; although the higher social classes did not speak French as their mother tongue by this time, French retained its social cachet, and the use of French expressions was an obvious way of signaling a higher social position. Even in present-day English, French-derived vocabulary is often stylistically marked as of a higher register; compare the difference in meaning between high-style *commence* and neutral *begin*.

French also affected word formation. On the one hand, compound forms, characteristic of Old English, were frequently replaced by simple borrowings (cf., *brecan* 'break,' *forbrecan* 'destroy'). On the other hand, French suffixes and prefixes were applied to native stems (e.g., *knowable*, *unspeakable*).

Typical Middle English

The heterogeneity of written Middle English means that a typical specimen of Middle English is not to be had. The following text from Scragg (1974: 31–32) is a version of the Lord's Prayer in a Central Midlands dialect of the 1380s (MS London, British Library, Royal 1.B.vi); it exemplifies some of the features previously discussed.

> Oure fadir, þat art in heuenys, halewid be þi name. þi kyngdom come. Be þi wille don as in heuene and in erþe. ȝiue to vs yis day oure breed ouer oþer substaunse. And forȝiue to vs oure dettes, as and we forȝiuen to oure dettouris. And leede vs not into temptacioun, but delyuere vs from yuel.

Modern Work on Middle English

The two most important recent single publications in Middle English studies are the *Middle English dictionary* (Kurath *et al.*, 1951–2001; also online), and *A linguistic atlas of late Mediaeval English* (LALME; McIntosh *et al.*, 1986). The former allows for a much more detailed investigation of the Middle English lexicon than has been possible hitherto. The parallel completion of the *Dictionary of the older Scottish tongue* (Craigie *et al.*, 1931–2002) means that the resources for the study of medieval lexicons

of Britain are now massively enhanced. In combination with the continued evolution of the *Oxford English dictionary*, and the imminent completion of the *Historical thesaurus of English*, these publications will allow a great leap forward in the diachronic study of vocabulary and its structure.

LALME has opened up a mass of unpublished evidence for investigation, and also, by localizing so many texts to particular places, means that a much greater range of dialectal grammars can be constructed than has yet been achieved. Follow-up projects on Early Middle English and Older Scots are currently under way.

The indispensable foundation, however, for the study of Middle English remains: the editing of texts. Some fashions in literary (as opposed to linguistic) study, however, militate against the usefulness of this enterprise; the modern practice: even in scholarly editions: is to make numerous silent decisions in editing Middle English texts. Such decisions disguise important linguistic features such as punctuation, marks of abbreviation, and even spelling.

Alongside these developments, theoretical work continues. Probably the most important descriptive milestones are the major histories, such as the second volume of the *Cambridge history of the English language* (Blake, 1992) and the single-volume *Oxford history of the English language* (Mugglestone, in press). Explanatory work is necessarily more controversial; probably the single most influential work on the historical study of English, with a special focus on Middle English, remains Samuels (1972).

English, Old English

C L Allen, Australian National University, Canberra, Australia

© 2006 Elsevier Ltd. All rights reserved.

Old English is the development of the language which was introduced into Britain by Germanic invaders in the 5th century A.D. and became the dominant language of what is now England excluding Cornwall, and also southern Scotland. Old English evolved gradually into Modern English, and any date given to delineate the different stages of the language must be somewhat arbitrary. The period covered by Old English spans c. 425 to c. 1100, and the language underwent extensive changes in this period. The comments made below about the phonology and grammar of Old English must be understood to apply to some of this period, but not necessarily all. By 1100, the accumulation of changes had become so great that it is appropriate to speak of Middle English.

While we do not know what the earliest Germanic people coming to Britain called their language, we find it referred to as *englisc* c. 1000, and *Engla land* (land of the Angles) used for the area where it was spoken. It is impossible to estimate the number of speakers throughout the Old English period, but William the Conqueror's Domesday Survey (1086) suggests an Anglo-Saxon population of between one and two million.

It is customary to recognize four basic dialects of Old English, distinguished from each other most prominently by phonological features but also by morphological and lexical peculiarities: Northumbrian (northern), Mercian (midlands), Kentish, and West Saxon (southwestern). It is tempting to attribute the main dialect differences to the premigration period on the continent, following the tradition beginning with the famous description of the Germanic invaders in Bede's *Ecclesiastical history of the English people*. Bede, writing in Latin in 731, says that the invasion force consisted of three tribes – Angles, Saxons, and Jutes – who founded separate kingdoms. But majority opinion of modern scholars stresses the complexity of political and social factors that presumably contributed to the creation of regional dialects in addition to the variation that would have come with the earliest Germanic settlers.

Our knowledge of Old English dialects and how they developed is limited by the sparseness of records in English until the 9th century. Because this was a period of political hegemony by Wessex accompanied by a burst of literary activity associated with Alfred the Great (who reigned from 871 to 899), the majority of surviving Old English manuscripts were written in the West Saxon dialect, and West Saxon became a sort of standard for writing in most areas of the country. For this reason, West Saxon is what is normally taught as Old English. Standard Modern English is not in a straight line of descent from West Saxon, but derives mainly from southeastern Mercian varieties for which our information in the Old English period is scanty.

Genetic Relationships

Comparison of Old English with other languages shows that it belonged to the Germanic subgroup of the large Indo-European family, which includes Old Saxon, Old High German, Old Frisian, Gothic, and Old Norse. An example of a major phonological feature that sets the Germanic languages off from the other Indo-European languages is the Germanic shift of stress to the initial syllable of every word (excluding certain prefixes). Using the comparative method, we can reconstruct a good deal of the vocabulary and morphology of Germanic; for example, Old English, Old Saxon, and Old Frisian share the form *ūs* 'us', which can be shown to have descended from the same form **uns* in Germanic. The word shows up as *uns* in Gothic and Old High German and *oss* in Old Norse.

Such comparison indicates that Old English, Old Frisian, and Old Saxon shared some sound changes which differentiated them from the other Germanic languages. In the example just cited, the nasal *n* has been lost before the fricative *s,* with compensatory lengthening of the vowel, in these languages, and similarities of this sort have caused Germanic scholars to refer to these three languages as 'Ingvaeonic' or 'North Sea' Germanic. A smaller grouping of Anglo-Frisian can be made within the Ingvaeonic group. Old English and Old Frisian were the only Germanic languages that fronted the Indo-European back vowel *a* to front *æ*. The Ingvaeonic languages share with Old High German some consistent similarities that differentiate them from the Scandinavian languages such as Old Norse on the one hand (where assimilation of the nasal to the fricative gives *oss* from **uns*) and Gothic on the other, and so a tripartite division of the Germanic languages into West, North, and East is traditional. This picture is complicated by the fact that the speakers of the West and North Germanic languages maintained a reasonable degree of contact with each other. Even while their languages were undergoing separate development, they retained a certain amount of unity and shared innovations. The result is that Old English was more like Old Norse than it was like the East Germanic Gothic.

Written Records

We can never know for certain how Old English sounded or everything about the grammar of the language, but there is a lot we do know. We cannot know the exact quality of the vowel in what was written as *mus* ('mouse'), for example, but we can tell that it must have been a long, high, back vowel. For one thing, comparison of the sister Germanic languages and the further history of the word in English (which saw the vowel become a diphthong) makes this the only candidate. For another, the Old English scribes adapted the Latin alphabet to represent their language, and it would have been perverse to use a letter to represent a sound that was entirely divorced from the sound it was used to represent in Latin.

Old English written records do not start appearing until *c*. 700 in quantities useful for studying the language of the time and its previous development from common Germanic. Prior to this, there are some inscriptions in the runes that the Germanic tribes used before their conversion to Christianity, when the Latin alphabet was adopted (*see* **Runes**). The earliest of these dates to the 4th or early 5th century. However, runes were mostly used for inscriptions, not literary activity. The runic inscriptions found in Britain are also few in number, although they provide us with very important information (sometimes open to more than one interpretation). We also have a copy of the law code of Æthelberht of Kent (d. 616), but it is contained in a manuscript from a much later period. The fact that anyone thought it worthwhile to write these laws down in English sets Old English apart from most vernacular languages of such an early period, when Latin was the only language used for such subject matter in much of Europe.

The earliest writings in the Latin-based alphabet, adapted slightly to deal with the sounds of Old English, are mainly glosses of Latin. These are invaluable sources of information about the phonology and morphology of the earliest period of Old English, but they cannot teach us much about Old English syntax. It is only in the time of Alfred the Great that materials become abundant. We have more remains of Old English than any other Germanic language of such an early period, covering poetry, religious material, medicine books, a grammar of Latin for English speakers, the *Anglo-Saxon chronicle*, and more, amounting to approximately three million words. Scholars are well served with electronic corpora, of which the Helsinki Corpus (see Kahlas-Tarkka *et al*., 1993) was the first. Such corpora have become an invaluable tool in the study of Old English morphology and syntax in particular.

From Germanic to Old English: Phonology

One of the most striking features of Old English phonology is that assimilation is found in more than one guise. Assimilation is found in most Germanic languages to some extent, but Old English underwent its own special assimilatory processes. A process usually known as *i*-umlaut is one of the most important developments of the prehistoric Old English period when Old English had separated from its sister languages but was not yet written down. The essence of this process was that a high front vowel or palatal glide in one syllable caused a back vowel in the preceding syllable to become a front vowel, to oversimplify greatly. This is a type of anticipatory assimilation, in which the speaker anticipates the vowel of an upcoming syllable by moving the tongue into a front position too early. An assimilation of an even earlier period involved the palatalization of velar consonants that were adjacent to front vowels or a palatal glide in the same syllable. Palatal stops have a tendency to turn into affricates, and this is what happened in Old English, with the result that Germanic **dīk* has come down to us as *ditch*.

The importance of syllable structure in Old English is seen in a process that deleted a final vowel after 'heavy' syllables, which either contained a long vowel or ended in a consonant cluster. Thus, the nominative plural form was *scipu* for 'ship' because the base *scip-* had a short vowel and ended in a single consonant, while *word* was either nominative singular 'word' or plural 'words' because the consonant cluster *rd* caused deletion of the plural suffix *-u*.

One interesting difference between Old English and the language that descended from it is that voicing was not a distinctive feature for most fricatives. In Modern English, [f] and [v], written as *f* and *v,* are perceived as two distinct sounds, as the difference between *fat* and *vat* illustrates. But in Old English, they were perceived as variants of essentially the same sound or phoneme. The labiodental fricative was pronounced as voiced [v] when surrounded by voiced sounds (such as vowels), but pronounced as voiceless [f] otherwise; e.g., although *deofol* was written with an *f*, it was pronounced more like modern *devil* than the spelling suggests.

Effects of Language Contact

Some everyday words borrowed from Latin such as *cēse* 'cheese' (from Latin *cāseus*) bear evidence of early sound changes and are likely to have entered the language prior to the invasion of Britain. The conversion to Christianity brought writing in the Roman

alphabet to the Anglo-Saxons (with the help of Irish missionaries). However, Anglo-Saxon churchmen preferred to use native resources for translating ecclesiastical concepts, e.g., *halig gāst* 'holy ghost' as the translation of *spiritus sanctus*; *spirit* was not used until the Middle English period.

Since Britain was inhabited by Celts before the Germanic invasion, one might suppose that Old English would show a great deal of Celtic influence, but the number of Celtic words borrowed into Old English, other than place names such as *Temes* 'Thames,' is exceedingly small. This is a pattern typical of an invasion, c.f. the retention of aboriginal place names by English settlers in the United States and Australia. Expert opinion varies greatly as to the number of Germanic migrants and the displacement of the Celts, but whether it was a case of language shift by the Celtic population or the spread of the language by the spread of the Germanic population, there is no convincing evidence of substratum Celtic influence on Old English grammar or phonology.

In contrast, there can be no question of very intimate contact with Scandinavian speakers, particularly in the northeast of the country, due to the Scandinavian raids that began in the 8th century, which later became determined attempts at settlement and culminated in Danish rule of the entire country by Cnut (1017–1035). Such contact cannot fail to have linguistic consequences, although the nature of those consequences is a matter of debate. Our uncertainty is exacerbated by the paucity of written records from the areas where contact with Scandinavian speakers was the greatest in Old English. Many of the consequences in English do not appear in texts until the very late Old English or Middle English period. However, the inflectional system of the *Lindisfarne Gospels,* an interlinear gloss that was added to a Latin text of the gospels in the 10th century in an area that had been under Scandinavian domination for more than a century, exhibits considerable modification of the inflectional system presented below. Many of these changes, such as the generalization of *-es* as the genitive singular inflection to declensional classes where it historically does not belong, are harbingers of more general changes of the Middle English period. This suggests that contact with Scandinavian speakers played an important role in shaping the dialects where contact was the greatest, with ramifications for the later development of Standard English. However, it is likely that in many instances, the effect of contact was essentially to take the brakes off linguistic changes that were already in progress.

With such closely related languages, it can be difficult to tell whether a word that is only recorded in the late Old English period or later is of native origin or a Scandinavian borrowing, but it is certain that large numbers of everyday words such as *take* which replaced native *niman* are of Scandinavian origin.

French influence in English mostly dates from after the Norman Conquest of 1066 and so mostly lies outside the Old English period, but contact with French did not begin with the Conquest; especially notable is that there was a strong Norman presence at the court of Edward the Confessor (reigned 1042–1066). Several French loan words entered the language in the Old English period, including *prūd* 'proud', first attested c. 1000.

Grammatical Characteristics

Modern English still exhibits much of the lexicon and many of the Germanic structural characteristics of Old English, but Old English is so different from Modern English that it must be learned as a foreign language. One of the primary distinctions between Old English and later English lies in the more elaborated inflectional morphology of Old English. For example, nouns and their modifiers were inflected according to two numbers (singular and plural), three genders (feminine, masculine, and neuter) and four cases (nominative, accusative, genitive, and dative). The distinctions were mainly made by suffixation, but also by mutation of the stem vowel, as in feminine nominative/accusative singular *bōc* 'book' but dative singular *bēc*. An instrumental case was distinguished to a limited extent, but it had mostly merged with the dative case, and a prepositional phrase was more commonly employed than the instrumental case. Here, as in many other places, prepositional phrases were already being used to supplement case marking. Few forms were unambiguously markers of a single combination of grammatical features; most masculine nouns did not distinguish the nominative from the accusative in either the singular or the plural, while most feminine nouns made this distinction in the singular but made no distinction between the non-nominative cases. Modifiers of the nouns, especially determiners, distinguished grammatical features more consistently, e.g., the masculine 'the stone' is *se stān* (nominative), *þone stān* (accusative), *þæs stānes* (genitive) and *þām stāne* (dative). Fewer distinctions were made in the plural even with the demonstratives, e.g., *þā stānas* 'the stones' could be nominative or accusative.

The more elaborate case marking system of Old English made a freer order of constituents possible than is found in Modern or even Middle English. 'The man killed the king' could be expressed as either *se man acwealde þone cyning* or *þone cyning acwealde se man*, because *se man* was

nominative, and identified the subject wherever it was positioned, and the accusative form *þone cyning* signaled the object. Already in Old English, however, the order Subject-Object (as in the first of our examples) was much more frequent than Object-Subject. This order was the usual one even when case marking would have made the grammatical relations clear without the help of word order.

The position of the verb was also variable. Old English exhibits the preference for verb-second order in main clauses and verb-final order in subordinate clauses found in the other early Germanic dialects, but in Old English, verb-second position in main clauses was not as regular as it is in, for example, Modern Dutch, and only about 50% of subordinate clauses have verb-final order. Order within the noun phrase was also variable but far from free, with the prenominal order Determiner Adjective Noun familiar from Modern English already the unmarked pattern. The postnominal order found in *men þa leofestan* 'most beloved people' (lit. 'people the belovedest') was mostly limited to vocatives and poetry, and is presumably a relic of more widespread postnominal positioning of modifiers in Germanic. The scene was set for further dependence on word order in the Middle English period.

English Lexicography

P Hanks, Brandeis University, Waltham, MA, USA and Berlin-Brandenburg Academy of Sciences, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Bilingual Beginnings

From earliest times, students have noted translations above words in foreign-language texts. Murray (1900) traces the origins of English lexicography to these notes, called 'interlinear glosses,' which are found in many Latin documents that survive from the Old English period. In some monasteries, interlinear glosses were collected into a document called a 'glossarium.' Such early glossaries originally listed the words in the order in which they were read in texts, but "as these manuscript lists came to be copied and re-copied, it was seen that their usefulness would be increased by putting the words and phrases into alphabetical order" (Murray, 1900). The development of these lists into more sophisticated language tools was given a great boost by the invention of printing, which enabled elaborate alphabetical lists of words, with explanations, to be reproduced in hundreds of copies. Lexicography has always been closely associated with printing and publishing. Johannes Gutenberg invented the printing press in Mainz, in about 1450, and by 1474, the new invention had been brought to England by William Caxton. In the century that followed, bilingual and multilingual compilations of technical terms in various domains, often with discursive and even anecdotal comments by the compiler, began to flourish. An example may be given from William Turner's *The Nature of herbes in Greke, Latin, Englishe, Duche & Frenche wyth the commune names that Herbaries and Apotecaries use*, published in 1548:

> **Anthenus.** *Anthenus* siue *Chamaemelon* is called in englishe *Cammomyle*, in duch *camillen*, in frenche *camomille*. Camomilla is deuided into three kyndes, the firste

English: World Englishes

B Kachru, University of Illinois, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

The conceptualization of the term 'world Englishes' is within a 'socially realistic' approach to language study (see, e.g., B. Kachru, 1981). The first linguist who, in a rather indirect way, provided such insight about what is now termed world Englishes was John Rupert Firth (1890–1960), the first holder of the chair of general linguistics at London University. In 1956, after his extensive experience in South Asia, Firth (1956: 97) observed:

> English is an international language in the Commonwealth, the Colonies and in America. International in the sense that English serves the American way of life and might be called American, it serves the Indian way of life and has recently been declared an Indian language within the framework of the federal constitution. In another sense, it is international not only in Europe but in Asia and Africa, and serves various African ways of life and is increasingly the all-Asian language of politics. Secondly, and I say 'secondly' advisedly, English is the key to what is described in a common cliché 'the British way of life.'

This observation, made over a half-century ago, exemplifies the linguistic pragmatism and social and functional realities of the English language in world context. Firth's earlier observations have been addressed in much more detail in the following years by a variety of theoretical and methodological frameworks (for a perceptive historical review, see Bolton, 2004).

Spread and Stratification

The cross-cultural and cross-linguistic diffusion of English may be viewed in terms of three phases. The first phase was initiated in the British Isles in 1535 when the Act of Union annexed Wales to England. The linguistic implications of this Act were far reaching, as outlined by Edwards (1993: 108):

> The most damaging section of the Act of Union, as far as the Welsh language was concerned and thus a significant element in its collective consciousness, was its emphasis on English as the language of preferment. English became essential for success. It specified "no personne or personnes that use the Welsshe speche or langage shall have or enjoy any manner of office or fees within the Realme of Onglonde Wales or other the Kinges dominions and exercise the speche or langage of Englische.

In 1603, Scotland also came under British rule, and with this territorial expansion, King James VI became King James I of England. The expansion continued, and in 1707 yet another non-English speaking region, Ireland and its indigenous languages of Celtic and Gaelic, were subsumed. This phase of expansion was notable for the consolidation of the dominance of English in the British Isles.

It was in the second phase of the diffusion that the diasporic varieties of English were transplanted across continents, notably to North America, Australia, Canada, and New Zealand. This phase involved a significant movement of native-English-speaking populations to new social, linguistic and cultural contexts. Although in total numbers this relocated population was limited, these groups, for example in Australia and New Zealand, developed influential and powerful English-using communities. As time passed, various strategies of educational planning, proselytization, and trading in the language were used to initiate – and increase – bilingualism in English.

The third phase of diasporic expansion introduced English into Asia and Africa. In contrast to the second phase, it brought English into contact with genetically and culturally unrelated languages in far-flung parts of the world. This diaspora provided a new ecology and, for the teaching of English, unprecedented challenges in terms of language contact, cultural contexts, norms, identities, and methodologies. Those challenges continue to confront the professionals in the new millennium.

This diasporic expansion laid the foundations for the use of the English language as cultural ammunition in all these territories and resulted in several indigenous varieties. The reactions to these transplanted varieties and their historical, social, educational, ideational, and cultural implications have ultimately resulted in the most articulate critical debates – both of agony and ecstasy (for further references, see B. Kachru, 1996).

The characterization of the stratification and functions of world Englishes within theoretical and pragmatic frameworks received a further stimulus in the 1970s. It was John Lyons (1978: xvi) who pointed out the parallels "between Labov's approach to linguistics and that of the 'British' school, which draws its inspiration from J. R. Firth." The 'socially realistic' paradigms – mixed with the activism of their proponents – resulted in consideration of linguistic diversity within Englishes as an integral part of social interaction and contextual realities (see B. Kachru, 1981).

Several schemas have been presented to characterize the diffusion of English and its global presence (see McArthur, 1993). One such model that has been

adopted in several studies since the 1980s, the Concentric Circles model (Figure 1), is discussed below in detail.

Concentric Circle Model

The concentric circles representation of the spread of English, proposed in 1985, is more than mere heuristic metaphor for schematizing the spread of English. This representation provides a schema for the contextualization of world varieties of English and their historical, political, sociolinguistic, and literary contexts. The characterization of world Englishes is primarily based on the following factors:

- the history of the types of spread and motivation for the location of the language
- patterns of acquisition
- societal depth of the language in terms of its users, and the range of functions that are assigned to the English medium at various levels in the language policies of a nation (e.g., in administration, education, and literacy)
- functional acculturation of the English language within the local culture and societies and its nativization in the society and its literary culture

Figure 1 Three concentric circles of World Englishes.

The term 'nativization' refers to the formal and functional changes the language undergoes at various linguistic levels (e.g., phonetic, lexical, syntactic, discoursal, speech acts, literary creativity). In other words, the diffusion of English over centuries involves geographical expansion into regions of the world that had distinct physical realities and social, cultural and linguistic identities. It is in such contexts that the English language acquired 'functional nativeness.' It is the extent of functional nativeness in terms of the range and depth of English in a society that determines its impact. The more such functions of English increase in a speech community, the more local identities the variety acquires.

The three circles are not static, but dynamic and changing. The dynamics of the English language in terms of its status, functions, and attitudes toward it are well documented in the case studies of, for example, Bangladesh, Sri Lanka, Malaysia, Indonesia, and even in several Francophone countries.

In historical terms then, the Inner Circle primarily, but not exclusively, comprises the L1 speakers of varieties of English: It is this circle, (e.g., Britain, United States, Canada, Australia, and New Zealand), that provided the springboard for transplanting the language in other parts of the globe. The Outer Circle includes the major Anglophone countries of Africa and Asia, including India, Nigeria, the Philippines, Singapore, and South Africa. The Expanding Circle includes China, Taiwan, Korea, and Saudi Arabia (for the dynamic nature of this circle, see Berns, 2005).

The three circles model, as McArthur (1993: 334) suggested, represents "the democratization of attitudes to English everywhere in the globe." In his view,

> [T]his is a more dynamic model than the standard version, and allows for all manners of shadings and overlaps among the circles. Although 'inner' and 'outer' still suggest – inevitably – a historical priority and the attitudes that go with it, the metaphor of ripples in a pond suggests mobility and flux and implies that a history is in the making.

World Englishes Speech Communities

The earlier canonical definitions of the concept of 'speech communities' do not capture the pragmatic and functional global realities of the English language. Consider, for example, the restricted definition of the term provided by Bloomfield (1933: 42): "a group of people who interact by means of speech." On the other hand, in Hymes's view (1974: 47–51), a

speech community is "a social, rather than linguistic entity" that shares "knowledge of rules for the conduct and interpretation of speech." The views of Firth (1957: 191) contrasted with that of sociologists and anthropologists, when he wrote:

> The study of linguistic institutions is thus more specific and positive and on the whole less speculative than the sociological study of societies. Sociologists and social anthropologists are much bolder than linguists in what they find it possible to state in general human terms. To what lengths sociological abstractions can be extended is well-exemplified in Pareto's theory of residues and derivations.

However, Firth also emphasized that a monolithic description of language does not convey the socially and contextually insightful characteristics of language. In his provocative way, Firth (1957: 29) wrote that the "unity of language is the most fugitive of all unities whether it be historical, geographical, national, or personal. There is no such thing as *une langue une* and there has never been."

The English-using speech communities involve multiple – and often complex – historical, ideational, functional, and attitudinal contexts. In the global context, these fast-growing communities demonstrate varying degrees of competence in the language and its uses in terms of the range of functions and hybridization. These speech communities are primarily of the following types.

- Monolingual users of the language whose one and only language of communication is a variety of English; for example, a large portion of the inhabitants of the United Kingdom, United States, Australia, and Canada. In these countries, too, the number of bilingual users or non-English-using immigrant populations representing multiple languages from Asia, Africa, the Caribbean, Latin America, and Europe is fast increasing.
- Bilingual users of English who acquire English as an *additional* language for communication in those domains of function in which their L1 is not used or is not considered functionally appropriate to use.
- Multilingual users in whose verbal repertoire English is yet another code of communication, and language-shift and alternation are a normal communicative strategy. This phenomenon has been well documented with reference to multiple Anglophone English-using speech communities in Africa, Asia, Europe, and in the United States and United Kingdom.
- Bidialectal speakers and those whose L1 dialect has not attained functional and attitudinal recognition, as is the case of Ebonics (African-American English) or Spanglish in the United States.

One major factor that distinguishes the international profile of English from that of other languages of wider communication is that it has more users now who have acquired it as an L2, L3, or L4 in their language repertoire (see Table 1).

Process of Nativization and Englishization

The speech communities of English in the Outer Circle use institutionalized varieties of English, which have the following characteristics:

- recognition of English in the overall language policy of the English-using nation (e.g., India, Nigeria, Singapore)
- an extended tradition of contact literatures in English that are recognized as part of the national literatures.
- social penetration of the language that has resulted in several social, ethnic or functional subvarieties (e.g., Singlish, Basilect, Bazaar English, Tanglish)
- distinct linguistic exponents of the process of nativization at various levels

Table 1 The statistics of World Englishes

Society	*Approximate population (million)*	*Percentage of L1/ L2 English users*	*Approximate totals (million)*
INNER CIRCLE			
United States	293		
United Kingdom	59		
Canada	32		
Australia	20		
New Zealand	4		
OUTER CIRCLE			
India	1000	33	330
Philippines	86	56	48
Pakistan	159	11	17
Malaysia	24	32	8
Bangladesh	141	5	7
Hong Kong	7	35	2
Singapore	4	50	2
Sri Lanka	20	10	2
EXPANDING CIRCLE			
China	1300	18	234
Japan	127	33	42
Indonesia	238	5	12
Thailand	60	10	6
South Korea	49	9	4
Vietnam	83	5	4
Myanmar	43	5	2
Taiwan	22	10	2
Cambodia	13	5	0.6
Laos	6	5	0.3

The above figures are 'guesstimates' based on various published resources.

- an extended range of localized genres and registers
- Englishized varieties of local languages, some of which may have even acquired distinct names (e.g., *Hinglish* or *Hindlish* of India)
- acculturation of the English language for articulating local social, cultural, and religious identities.

The process of nativization is one major linguistic dimension of acculturation of world Englishes: this acculturation is evident in Anglophone Asian and African functionally localized contexts.

The two processes of nativization and Englishization are Janus-like, two faced. One face reflects the impact of contact and convergence with other languages – Asian and African – at various linguistic levels. The second face shows the impact that the English language and literature have on other languages and literatures of the world. Englishization is not restricted to phonology, grammar, and lexis, but can have a deep impact on discourse, registers, styles, and literary genres in contact literatures in Englishes (see, e.g., Thumboo, 1992; Dissanayake, 1997; Y. Kachru, 1997; B. Kachru, 2003; Y. Kachru, 2003; B. Kachru, 2005).

The process of Englishization is evident in three major geographical regions associated with the spread of English:

1. Traditional regions of cultural and literary contact in which a number of cognate languages of English are used (e.g., in Western Europe and parts of Eastern Europe)
2. Anglophone, geographically noncontiguous with English, regions of the Raj, which include the Outer Circle of English, and have, in a genetic sense, unrelated or not-closely related languages (e.g., parts of Africa and Asia)
3. Expanding Circle, which includes the rest of the world (e.g., Japan, China, the Middle East, and Latin America).

In defining the nativeness of varieties of Englishes, a distinction may be made between genetic and functional nativeness. Genetic nativeness refers to the historical relationship of the languages in contact, and functional nativeness to the domains of use of English, the range and depth in social penetration, and the resultant acculturation. A profile of the functional nativeness of a variety of English includes these factors:

- sociolinguistic status of a variety in its transplanted context
- range of functional domains in which a variety is used
- creative processes used to construct localized identities
- linguistic exponents of acculturation
- types of cross-over contributing to canons of creativity
- attitude-specifying labels used for the variety of English.

The second diaspora of English has raised a variety of questions that are unique to transplanted Englishes and continue to be debated in the literature (see, e.g., B. Kachru, 1988, 1996; Mufwene, 2001; B. Kachru, 2005).

Models of Description

The canonical models of English continue to be viewed in terms of privileged British and American varieties of the language. The theoretical, methodological, and ideational issues raised by such an attitude have been extensively – and passionately – articulated in the literature in recent years. This debate has acquired a prominent position in the conceptualization of world Englishes. There are essentially three types of speech fellowships of world Englishes: (1) those that are canonically considered privileged and norm-providing – the Inner Circle, (2) those that have functionally acquired the status of norms and are pragmatically relevant in their sociolinguistic context – the Outer Circle, and (3) those that in many respects continue to be attitudinally dependent on external norms, primarily from the Inner Circle – the Expanding Circle (see Berns, 2005).

Conceptual Myths

The articulation of the following six myths in the conceptualization, methodology, and pedagogy of world Englishes has resulted in the 'paradigms of marginalization.' These paradigms are essentially based on age-old following fallacies:

1. World Englishes in Anglophone Asia and Africa are acquired and used to interact with canonical 'native' speakers of English.
2. World Englishes are acquired to learn the Judeo-Christian traditions as articulated in American and British cultural and literary values and traditions.
3. The Inner Circle Englishes are primary and standard 'model providers' for teaching and acquiring communicative competence in the language.
4. Conceptually, all varieties of world Englishes in Outer Circle are essentially *deficit* or *interlanguage* varieties.
5. Historically it is the Inner Circle that has provided – or should provide – models and standards for ELT

pedagogy, creativity, and canonicity of Englishes across Anglophone regions and cultures.

6. The arms of codification of the English language, established – and imposed – by agencies of the Inner Circle, should ideally control the variation and diversity in world Englishes (see the Quirk-Kachru controversy, discussed in detail in Tickoo, 1991).

Constructing Identities of Englishes

The controversial modifiers of the term 'English' that are frequently used to characterize the post-colonial diffusion and stabilization of the English language across cultures and languages include 'new Englishes' and 'international,' 'global,' or 'world English.'

The term 'New Englishes' was primarily – though not exclusively – used for the institutionalized varieties in the Outer Circle. All the 'new' varieties are transplanted (diaspora) varieties that have a presence on almost every continent. However, the use of the modifier 'new' for such Englishes is a misnomer – historically, contextually, and in terms of their acquisition, as some of them pre-date some Inner Circle varieties.

The conceptualization of 'world Englishes' (and not 'world English'), in the sense in which it is used here, goes back to the 1960s. Its formal and functional implications were discussed in 1978 in two independently organized conferences in the United States: one at the East-West Center at Honolulu, (April 1–15) and the other at the University of Illinois at Urbana-Champaign (June 30–July 2). The Honolulu conference concluded with a statement and agenda for the future recognizing that "English used as an international and auxiliary language has led to the emergence of sharp and important distinction between the uses of English for international (i.e., external) and intranational (i.e., internal) purposes."

In addition to this distinction between the uses of English-using speech communities, the statement further distinguished between "those countries (e.g. Japan) whose requirements focus upon international comprehensibility and those countries (e.g. India) which in addition must take account of English as it is used for their own national purposes." The Honolulu conference also expressed concern that "[s]o far as we know, no organization exists that takes into account of any language in the light of this fundamental distinction."

The University of Illinois conference, in contrast, "broke the traditional pattern of such deliberations: no inconvenient question was swept under the rug. The professionals, both linguists and literary scholars, and native and non-native users of English, had frank and stimulating discussions" (Kachru, 1997: 210).

The scholars present, almost all from Anglophone countries – including, Africa and Asia, as equal partners – discussed with refreshingly fresh perspectives the sociolinguistic and linguistic profile of each English-using country in terms of the functional range of their varieties of Englishes and the social depth of the penetration of the language. What emerged were fascinating worldwide profiles of nativization and acculturation of world Englishes and construction of their identities, attitudes, and functions. It was through such discussions that a socially realistic and pragmatically appropriate preliminary framework developed.

This socially realistic framework represents the formal and functional variations, divergent sociolinguistic contexts, and histories of world Englishes. It is through such contextual insights that the bilinguals' creativity, at various levels, acquires a social and functional meaning. The concept underscores the 'WE-ness' of the medium, its distinct nativeness determined in cultural, linguistic, and ideological contexts of Anglophone communities. Such cross-cultural functions of the medium acquire their own semantic signals in which the traditional dichotomies and frameworks demand alternative approaches. There is recognition of the fact that different methodologies may be needed (e.g., literary, linguistic, and pedagogical) to capture and construct the altered identities represented in the medium in Englishes of the world. The pluralization of the canonical term 'English' does not suggest 'divisiveness' in the English-using speech communities, but rather the recognition of a unique functional reality of the language: the diversity of the medium and its assimilative qualities in multiple pluralistic, linguistic, and cultural contexts.

These functional, contextual, and ideational connotations – and realism – are absent, as mentioned above, in such terms as 'international English,' 'global English,' or 'world English.' The term 'international' is misleading in more than one sense: it signifies an international English in terms of acceptance, proficiency, function, norms, and intelligibility. These presuppositions are far from the real world of Englishes in the world contexts.

The other concept currently presented to represent the global – or some times a regional – medium is 'lingua franca English.' This term was originally restricted to the intermediary contact language (*Vermittlungssprach*) used by the Arabs and the Turks as a maritime jargon in the Levant. It primarily signifies a language of commerce (e.g., Italian around the Adriatic Sea). Each variety in the Outer Circle,

as in the Expanding Circle, has its subvarieties in terms of functional connotations, domains, and attitudes toward localized varieties of Englishes and their cross cultural and cross-linguistic communications. Yet, the Inner Circle has made no serious efforts – socially, methodologically, or pedagogically – to recognize their status and currency.

One often-quoted interpretation of the concept of world Englishes was provided by McArthur (1993: 334) when he referred to the logo-acronym of the journal *World Englishes* (which started in 1984), which "serves to indicate that there is a club of equals here." In this interpretation, the emphasis is on "the democratization of attitudes to English everywhere on the globe," and it, as McArthur perceptively pointed out, dissolves the trinity of ENL, ESL, and EFL nations.

The linguistic, cultural, canonical, and literary implications of the diffusion of English beyond the Inner Circle are discussed in, for example, Dissanayake (1997), Thumboo (1992), and B. Kachru (1988, 2005).

World Englishes and Conceptual Frameworks

The theoretical, methodological, and ideological questions related to world Englishes go beyond language pedagogy, which was the primary concern before the 1950s. In the post-1960s period, several sacred linguistic cows of theoretical and applied linguistics as applied to world Englishes have been under attack as a consequence of several developments: insights gained by critical sociolinguistic paradigms, the articulation of identities with the language, and altered dynamics of the functions of English in post-colonial linguistic and cultural contexts. One thinks of, for example, the earlier theoretical and methodological emphasis given to such concepts as interference, interlanguage, and fossilization in paradigms of language acquisition. There was very little – if any – awareness of the pluricentricity of Englishes in the Outer Circle or of developing literary and cultural canons and nativized registers and genres in world Englishes in Africa, Asia, and the diasporic writers in the Inner Circle. After the 1960s, a vibrant debate started about several pedagogical issues, such as idealized models for the codification of English, the cross-linguistic claims made for teaching methods and methodologies, and English-language teaching materials developed, published, and often exported by the English-language teaching 'experts.'

Two often-articulated descriptive and prescriptive questions – specifically about the Outer Circle varieties – are the following: what criteria may be used to determine a difference between an error (or mistake) and an innovation? And, what variables determine intelligibility for varieties of world Englishes across cultures and languages?

In his extensive empirical research on the latter topic, Smith (1992) viewed intelligibility in a pragmatic communicative context by making a distinction among intelligibility (word utterance recognition), comprehensibility (word utterance meaning [locutionary force]), and interpretability (meaning behind the word/utterance [illocutionary force]). Smith and Nelson (1985) have also discussed some issues that should be on the agenda of any researcher studying intelligibility.

Literary Creativity, Canonicity, and World Englishes

The creative linguistic processes that result in competence in two or more languages are termed 'contact' or 'interference' varieties. The underlying process in the construction of contact literary texts is that of hybridization, as reflected in bilinguals' (or multilinguals') creativity. Such texts are designed with a blend of linguistic features from two or more – related or unrelated – languages. The concept of 'contact literatures' thus brings to the English language the multilingual and multicultural contexts of, for example, Africa and Asia. These varieties of English have acquired stable characteristics in terms of pronunciation, grammar, lexis, discoursal, and stylistic strategies. These traditions are often blended with local subvarieties of English, (e.g., Nigerian Pidgin in Nigerian English, Singlish in Singapore English, Bazaar or Babu English in Indian English). In such contact situations, the English language is a medium that has been, pragmatically and contextually, localized to adapt to – and to represent, as elegantly claimed by such writers as Raja Rao and Salman Rushdie (India), Chinua Achebe and Wole Soyinka (Nigeria), Edwin Thumboo and Catherine Lim (Singapore), and F. Sionil Jose (the Philippines).

It is 'contact' at various levels (linguistic, social, and cultural) and the resultant nativization that contact literatures represent in literary and cultural canons that are distinct from the Judeo-Christian canons. These processes thus ultimately result in, say, the Africanization or Asianization of world Englishes.

The term 'interference varieties' – though attitudinally loaded – is yet another label to conceptualize the contact varieties of English and the bilinguals' creativity. The interference varieties, as Quirk *et al.* (1985: 27–28) recognized are

> so widespread in a community and of such long standing that they may be thought stable and adequate enough to be institutionalized and hence to be regarded as varieties of English in their own right rather than stages on the way to more native-like English.

All such varieties, as shown in numerous studies, have formal and functional identificational features that represent the linguistic processes at various levels: grammar, phonetics, lexis, discourse, speech acts, genres, and indeed literary creativity (see Smith and Forman, 1997; B. Kachru *et al.*, in press). These studies are of three types: variety-specific (e.g., Indian English, Singapore English, Nigerian English), area-specific (e.g., South Asian English, West African English, Southeast Asian English), or of larger geographical regions in terms of linguistic, literary, and sociolinguistic areas (Africanization or Asianization).

The study of bilinguals' creativity demands recognition that the institutionalized Englishes have an educated variety and a cline of subvarieties, that writers in contact literatures engage in 'lectal mixing,' and that in such texts there are style shifts related to the underlying context of situation. In contextual terms, style shifts result in the construction of altered discourse strategies, speech acts, and registers. In discussing such creativity in world Englishes, Thumboo (1992: 270) argued the following:

> This challenge confronts almost every bi-or multilingual writer. His bilingualism is one of three broad types – proficient, powerful, or limited; his position in this cline is not static, because quite often one language gains dominance. A bilingual person has at least two language universes, and each language works with its own linguistic circuits. How the two associate depends on whether the languages as neighbors inhabit the same space and time and can bend to serve creative purposes.

There is thus multicanonicity in world Englishes that blends two or more 'language universes' in their creativity; the interlocutors in Englishes have a variety of linguistic, cultural, social, and literary traditions – a speaker of a Bantu language interacting with a speaker of Japanese, a Taiwanese with an Indian, and so on. The traditional and much discussed and canonical 'native speaker' may rarely be part of such interactions in Englishes. The linguistic historical analogues that come to mind – though not necessarily parallel to world Englishes – are that of Latin in medieval Europe (Kahane and Kahane, 1979) and of Sanskrit in traditional South Asia and beyond.

The Pandora's Box and World Englishes

The shared strands of current debates on world Englishes include the following seven major contextually, attitudinally, pedagogically, and linguistically relevant issues:

1. The demythologization of conventional sacred cows model initiated and nurtured by the Inner Circle constructs of English (see B. Kachru, 1988; Quirk, 1988)
2. The ecologies of multilingual Englishes, specifically in the contexts of Africanization and Asianization of Englishes (see Mufwene, 2001; B. Kachru, 2005)
3. The increasing expression of bilinguals' creativity in the Outer Circle and its implications on traditional canons and canonicity
4. The theoretical, methodological, and pedagogical implications of the increasing depth and range of Englishes (B. Kachru, 2001)
5. The issues of intelligibility in cross-cultural and cross-linguistic communication
6. The evaluation of ethical practices related to forms, functions, and pedagogy (see, e.g., Baumgardner and Brown, 2003; Dhillon, 2003)
7. The motivation of power and politics and the role of initiators of arms of control (Phillipson, 1992).

Environment and Language

P Mühlhäusler, University of Adelaide, Adelaide, Australia

Introduction

The notion of environment, like that of language, is a complex one, and there are a number of views on the most appropriate approach to this topic. The title of this article suggests that they can be treated as independent entities and correlated to one another. Moreover, it suggests that language is central, and that the environment surrounds this center. This implies that that the principal task of the investigator is to look for significant correlations between the two. The correlational approach contrasts with the view that languages are integrated with their environment and that correlations therefore are not of central concern.

Whenever the coverage of a discipline such as linguistics is extended, problems of definition arise. I comment here on the notion of 'environment of language' first and turn to attempts to define 'language' in the next section.

Environment of language has been characterized differently by different writers. Sapir (1912: 227) distinguishes between physical and social environment but cautions that:

> The mere existence, for instance, of a certain type of animal in the physical environment of a people does not suffice to give rise to a linguistic symbol referring to it. It is necessary that the animal be known by the members of the group in common and that they have some interest, however slight, in it before the language of the community is called upon to make reference to this particular element of the physical environment. In other words, so far as language is concerned, all environmental influence reduces at last analysis to the influence of social environment.

One such social influence that has received much attention in recent years is how different social roles of men and women are reflected in gender-specific language and discriminatory language use. Similarly, a number of ecofeminists have argued that man-made language is a root cause not only of social discrimination but also of unhealthy environmental attitudes.

Perhaps the best-known characterization of the environment of language is given by Haugen (1972: 325), who pointed out that the search for an appropriate definition of 'environment' might lead one's thoughts first to the referential world to which language provides an index. However, this is the environment not of the language but of its lexicon and grammar. The true environment of a language is the society that uses it as one of its codes.

Haugen further limits his investigation to the linguistic environment of language (i.e., the users, the relation to other languages, and the agencies concerned with the form and use and attitudes, but not their relationship to the natural environment). Haugen's ideas reflect his experience of Norway, with its competition in colonial days between Danish and Norwegian, and in independent Norway between three competing proposals for a national language. He was furthermore influenced by his experience of migrant languages in the United States, and his observations of language in modern nation states are repeated in many of the pre-1990 writings on this topic (e.g., the contributors to Enninger and Haynes [1984]).

In more recent years, the notion of environment of language has been widened considerably. Fill (1993) includes parameters such as age and gender into the ecology of language and, in the wake of the growing awareness of a worldwide environmental crisis, the relationship between language and the natural environment has become a focus of research interest. The question of whether environmental problems are in part a consequence of a growing mismatch between the contours of language and the contours of the natural environment has been asked by Mühlhäusler (1983), Trampe (1990), Halliday (1992), and Fill (1993).

There are four logically possible relationships between languages and their environment, all of which have been the subject from time to time of different schools of linguistics: the independency hypothesis (Chomsky, cognitive linguistics), language is constructed by the world (Marr), the world is constructed by language (structuralism and poststructuralism), and language is interconnected with the world – it both constructs and is constructed by it (ecolinguistics).

In the emerging discipline of ecolinguistics (Fill, 1998; Mühlhäusler, 2003), all of these relationships are considered, though the importance of the independency view of language has been greatly reduced.

Linguists continue to differ on the kinds of relationships they regard as most important and on what aspects of the world are perceived as most influential. Regarding relationships, the majority of writers on language and environment continue to emphasize the central role of competition (Haugen, 1972; Mufwene, 2001). The experience of competition between the nation states of Europe seems to be the metaphorical basis for this emphasis, but in numerous

traditional societies, small languages have coexisted with larger ones without any danger of them being lost. Ecolinguists such as Fill (1993) note that competition is far less important in nature than commonly believed, and that more than 80 percent of all interactions between natural species are either beneficial or neutral.

The aspects of the world deemed most important by linguists are social factors – contact with other languages and varieties as well as the metalinguistic beliefs and practices prevailing in a language community. The interaction between languages and their natural correlates have remained subsidiary to this, partly because earlier attempts to explore the nature of language with reference to their environments have been fairly crude. The notion that language and environment adapt to one another is recent, and as yet not fully developed, but progress has been made in the study of the relationship between linguistic diversity and the diversity of natural life forms (Nettle, 1999), between conservation, biology and language conservation (Mühlhäusler, 2003; Harmon, 2002; Maffi, 2001), and between language development and environmental conditions (Mühlhäusler, 1996).

Metaphors and Definitions of Language

The primary purpose of definitions is to create a research tool. The question of a suitable definition of language needs to be distinguished from the question of its ontology – the actual nature of language. Haugen's notion of a 'language ecology,' in which languages interacted with other languages and their environment, was not conceived as a claim about the essential nature of language, and he made it clear that this was not a suggestion that languages are organisms. Language ecology for a long time remained a useful metaphor that helped answer questions such as the disappearance of minor European languages and the causes of language conflict.

Those who use the notion of language ecology metaphorically have held varying views on the nature of language, ranging from that a mental organ to that of a social semiotic. However, ecolinguists, similar to integrational linguists, question the independency view of language and claim that, as language is inextricably linked to wider ecology, its ontology is that of an ecological phenomenon (Finke, 2002; Mühlhäusler, 2003).

Themes in Language and Environment

There are numerous approaches to the relationship between language and environment (surveyed in Mühlhäusler, 2003). I restrict the discussion here to those that start at the linguistic end (i.e., studies focused on the properties of words, grammar, and discourse).

Properties of Words

A focus of many present-day writers is the proliferation of neologisms that have emerged in the wake of growing awareness of the global environmental crisis: Most of the new terms are the result of terminology planning rather than spontaneous innovation, an example being the INFOTERRA Thesaurus (1997). Most of the new terminology originates in English, is highly technical, and consequently abounds in abstract nouns, multiword formation, and words of Latin and Greek origin. The appropriateness of such formations in environmental discourse has been questioned by numerous writers (summarized in Harré *et al.*, 1999), who point out the dangers of substituting greenspeak for environmental action. They have also drawn attention to the trend to introduce deliberately misleading terms to deflect public attention of problematic practices. Examples of the latter category are 'land reclamation' for wetland drainage, 'sustainable agriculture' for agriculture aimed at sustainability, 'vegetation manipulation' for clear felling, and 'game management' for hunting of wild animals.

Critical ecolinguistics, pioneered by Halliday in 1992, exposes the growthism (portraying growth as semantically unmarked and positive: bigger is better), classism, and speciesism (privileging the human perspective: man is the master of creation) of Western languages, and there are now numerous studies on these trends (see Fill and Mühlhäusler, 2001). The dominance of inappropriate English expressions in the environmental domain is spread through translation. European Union legislation, for instance, requires intertranslatable environmental terminology, and the new member states model their terms on existing English expressions. The resulting process can be characterized as semantic colonization. Conversely, environmental concepts from traditional languages spoken in nonindustrial societies rarely find their way into the green terminology that has developed in English and other world languages over the last decades.

Properties of Grammatical Constructions

Studies beyond the level of green lexicon are rare. Halliday's (1992) suggestion that grammars are the fossilized memory of experience has prompted a number of writers to explore how radically different grammars (e.g., ergative vs. nominative-accusative) reflect fundamentally different attitudes to the relationship

between humans and nature. They point out, for instance, that ergative languages, or languages in which cause–effect relationships are difficult to encode, reduce the disposition of their speakers to change their environment. Noun classification systems differentially emphasize or deemphasize the solidarity of humans with other life-forms, as does the inclusion or exclusion of animals in the same gender class as humans.

An extensive list of environmentally problematic grammatical practices in modern European languages is given by Chawla (1991). These practices include passive constructions in environmental texts, which suppress the actor or human agency in environmental degradation, and nominalizations, which reduce processes to abstract objects, as in 'water condenses' becoming 'condensation occurs.'

Properties of Texts and Discourses

The Whorfian idea of linguistic determinism suggests that language structure predisposes language users to develop specific attitudes and actions. It fails to account for the observation that within one and the same language, very different discourses about environmental matters can be produced. For instance, different language is used by developers and environmentalists to describe the same landscape. These differences involve lexical choice as well as the differential use of pronouns. Thus, 'we' can refer to either 'humans and nature' or 'developers and clients.' Similar differences between conservationists' and seal hunters' discourses have been described by Martin (1986). When examining discourses from a narrative perspective, it is found that groups with opposing views on environmental issues typically use the same narrative structures, the difference being the choice of who are the heroes and who are the villains (see Harré *et al.*, 1999). Very different perceptions of the environment are created by the economic, moral, and scientific macro discourses. These discourses often raise conflicting perceptions, particularly on issues such as the need to reduce overpopulation of animals to prevent destruction of their habitat. Irving (2002) describes the cyclical discourses about the koalas of Kangaroo Island. These animals, which enjoy a charismatic status on the Australian mainland, were introduced to the island in the 1920s, where they multiplied to plague proportions. Scientific arguments for the cull or reduction of the koalas have been repeatedly put forward and rejected on moral and economic grounds, and the matter remains unresolved. Another domain in which scientific discourses clash with economic and moral discourses is ecotourism (Mühlhäusler and Peace, 2001).

Environmental Metaphor

Because environmental awareness is of recent origin in Western societies, environmentalist language not only developed numerous new terms but also developed a number of metaphors. Such metaphors have been the focus of several studies (Harré *et al.*, 1999; Döring, 2002; Mühlhäusler, 2003). Environmental metaphors can be analyzed as cultural core metaphors (e.g., our environment is the book written by God, a larder, or a machine), rhetorical devices that help reconcile conflicting discourses (one buys products that do not cost the earth), heuristic devices (the 'sink' metaphor has been employed to explore the possibility of reducing global warming through heat sinks and carbon sinks), and rhetorical devices to justify environmental policies such as population control (lifeboat earth, spaceship earth).

Those concerned with the effect of key metaphors on environmental perceptions and actions note that the different players in the environmental debate live by a range of different metaphors. This makes both local and global agreement on environmental action very difficult.

Critiquing environmental metaphors is a key concern of many ecolinguists. Ecofeminists have pointed out that the metaphors of male explorers such as 'virgin territory' or 'penetrating the interior' are essentially rape metaphors. Similarly, managerial, corporate metaphors such as 'environmental management system,' 'environmental auditing,' 'environmental performance evaluation,' or 'environmental objectives' have received much criticism, as has the metaphor of reification, the portrayal of situated processes as timeless, bounded objects.

Ongoing Dichotomies

In what has been said thus far, the notions of language and environment have been seen as distinct. This view contrasts with the ecological or biocultural approach (Maffi, 2001), which replaces the dualistic view of the relationship between language and the environment with a more complex holistic notion that nature and culture, language and environment are inextricably linked and that the diversity of linguistic and cultural perspectives is a key factor in biological diversity and environmental health. It has been proposed (Harré *et al.*, 1999; Maffi, 2001) that the fit between traditional languages and their natural environment was brought about by the necessity of languages to match the diverse environments in which they are spoken. This leads to the conclusion that the loss of linguistic diversity is a key factor in the loss of biological diversity.

Just as natural ecologies are seen as structures and are defined by functional interconnections between their inhabitants and their habitats, linguistic diversity is seen as similarly structured, with small languages being important for the viability of larger ones and vice versa. Haugen's metaphor of a competitive marketplace has been replaced by a metaphor of protective layers (Mühlhäusler, 1998). In a layered language ecology, the smallest local vernaculars are sheltered from neighboring vernaculars by intercommunity Pidgins, regional Pidgins, and larger lingua francas. The layer metaphor seeks to explain why small vernaculars have become very vulnerable when intercommunity languages are replaced by a single, large, national language.

Applications and Prospects

Any linguistics that increases the number of parameters it considers provides for a larger number of applications and explanations. The language and environment approach has begun to be applied to language planning, and Liddicoat and Bryant (2000: 305) suggest that "where planning does not consider ecology the result is typically environmental damage, in language as much as in other areas."

Increasingly, language planners consider the social and natural environments of their activities, and in particular the question of whether the introduction of new practices (e.g., literacy or Information Technology), into the environment of indigenous traditional languages might have an adverse effect on their viability. The suggestion that misleading labeling can lead to environmental degradation has been applied to environmental education and signage and has led, for instance, to the renaming of small Australian land animals (previously referred to as rats) with names that remove the perceived undesirability that 'rat' suggests. Examples include Djoorri for the common rock-rat, Palyoora for the plains rat, Tooaranna for the broad-toothed rat, and Rakali for the water-rat (Braithwaite *et al*., 1995).

Critical environmental linguists have proposed a number of changes in product labeling (e.g., more careful use of the descriptor 'natural' in the United Kingdom) and in the wording of environmental impact assessments. Interestingly, in Wales there is now a requirement of a linguistic impact statement. Critical reassessment of the term 'natural' is also encountered in the debate about causes of so-called natural disasters such as landslides, floods, or droughts, which often turn out to have been triggered by human activity. The idea of languages having an environment or being part of the ecology has produced significant development in the areas of literacy education (e.g., Barton, 1992) and L2 education. Language learning is now seen to take place in a classroom environment or wider social environments that affect its success.

As yet, most writings on language and education have been of a theoretical or critical nature rather than empirical, and the findings that have been made in recent years have been slow in reaching wider public awareness and policy making. Organizations such as Terralingua (http://www.terralingua.org), or events such as the 2004 World Expo of Language and Cultures in Barcelona, may help to popularize the ideas addressed here. The establishment of a new publication focused on an ecological approach to language planning (*Current Issues in Language Planning*) should promote new departures in language planning practices.

Epistemology and Language

H Jackman, York University, Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

There has always been a close relation between theories of language, mind, and knowledge, and over the past 80 years, the connection between epistemology and language has typically manifested itself in one of two ways.

First of all, reflection on language has been used to give an account of the meaning of epistemic terms like 'know,' 'rational,' and 'justified,' which have nontrivial, often antiskeptical, consequences. For instance, Strawson (1952) argued that using induction is an essential part of what we *mean* by having 'reasonable' or 'justified' beliefs about the world around us, and so it made no sense to worry about the 'rationality' or 'justification' of induction. More counterintuitively, Malcolm (1952) argued the there was a "strong" sense of "know" in which it was impossible for him to doubt that he knew that there was, say, a pen in his hand, since he would have counted *nothing* as evidence against this claim.

This sort of 'ordinary language' approach has generally (and justly) fallen out of favor, as its presuppositions about the meaning of epistemic terms are now viewed as implausible. However, a related strategy that drew from the same Wittgensteinian roots (Wittgenstein, 1969) has emerged in the form of contemporary 'contextualist' epistemologies. These argue that our use of 'know' and related terms is context sensitive in ways that allow the skeptic's claim that we know nothing about, say, the external world *and* our everyday claims to know commonplace facts about the world to *both* be true. It's just that the standards for applying the term 'knowledge' (like those for the application of terms like 'tall') shift from context to context (DeRose, 1995; Williams, 1991).

Such 'therapeutic' approaches do not so much solve traditional skeptical problems as show them to rely upon misunderstandings about how our epistemic terms operate. There is, however, a second way in which philosophical theories of language can be used to respond more 'directly' to traditional epistemological problems.

Epistemology and Language

H Jackman, York University, Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

There has always been a close relation between theories of language, mind, and knowledge, and over the past 80 years, the connection between epistemology and language has typically manifested itself in one of two ways.

First of all, reflection on language has been used to give an account of the meaning of epistemic terms like 'know,' 'rational,' and 'justified,' which have nontrivial, often antiskeptical, consequences. For instance, Strawson (1952) argued that using induction is an essential part of what we *mean* by having 'reasonable' or 'justified' beliefs about the world around us, and so it made no sense to worry about the 'rationality' or 'justification' of induction. More counterintuitively, Malcolm (1952) argued the there was a "strong" sense of "know" in which it was impossible for him to doubt that he knew that there was, say, a pen in his hand, since he would have counted *nothing* as evidence against this claim.

This sort of 'ordinary language' approach has generally (and justly) fallen out of favor, as its presuppositions about the meaning of epistemic terms are now viewed as implausible. However, a related strategy that drew from the same Wittgensteinian roots (Wittgenstein, 1969) has emerged in the form of contemporary 'contextualist' epistemologies. These argue that our use of 'know' and related terms is context sensitive in ways that allow the skeptic's claim that we know nothing about, say, the external world *and* our everyday claims to know commonplace facts about the world to *both* be true. It's just that the standards for applying the term 'knowledge' (like those for the application of terms like 'tall') shift from context to context (DeRose, 1995; Williams, 1991).

Such 'therapeutic' approaches do not so much solve traditional skeptical problems as show them to rely upon misunderstandings about how our epistemic terms operate. There is, however, a second way in which philosophical theories of language can be used to respond more 'directly' to traditional epistemological problems.

The second approach focuses not upon the meaning of specific terms, such as 'know,' but rather upon our ability to derive epistemological conclusions from any *general* account of meaning that outlines the limits of our representational capacities. The limits of our representational capacities determine the extent to which certain sorts of skeptical doubts are legitimate and a general theory of language could thus be used as a weapon against skepticism.

To take an illustrative example, classical verificationism, which understood the meanings of our utterances in terms of the experiences taken to verify them, had clear antiskeptical consequences. If the meaning of a statement like 'there is a pen in front of me' were determined by the experiences standardly used to confirm it, and I could *know* that I'm having such experiences, then I could know that there is a pen in front of me. The verificationist theory of meaning thus blocked skepticism regarding the transition from knowledge of our experience to knowledge of the 'external' world (Ayer, 1936). Of course, it did this at the expense of making problematic our being able to talk or think about anything other than our own experiences.

This general pattern carries over to most other attempts to draw epistemic conclusions from a general theory of linguistic representation. Any substantial account of meaning that treats it as determined by some aspect of our *use* will give a certain amount of epistemic privilege to that meaning-determining aspect, and such privileging may undermine various local or global skeptical worries. However, the antiskeptical advantages that use-based accounts of meaning bring often come at the cost of having to endorse antirealism about facts that we intuitively take to be more 'objective.'

For instance, 'descriptive' theories of meaning took what we meant by (many of) our terms to be determined by (some of) the descriptions we associate with them. 'Pen,' say, gets its meaning by having a description like 'cylindrical handheld artifact used to write with ink' associated with it. However, if such descriptions determined the meaning of the terms involved, then they could be known to be true in virtue of those meanings, and thus a purely 'linguistic' explanation of the possibility of *a priori* knowledge becomes available. We could know *a priori* that all pens are artifacts, because this proposition followed from the meaning of 'pen.' *A priori* truths were so knowable because they were analytic, that is, true in virtue of their meaning (Ayer, 1936).

In addition to the general doubts about analyticity stemming from Quine's work (1951), the description theory suffered from the fact that many of the propositions that it suggested that we knew *a priori* seemed, on reflection, not to be so knowable. There are, as Putnam stressed, things that we *actually* apply the term 'pen' to, and if *they* turned out not to be artifacts (say, they were alien organisms that were born rather than manufactured), then we would conclude that pens were not artifacts, not that there were no pens (Putnam, 1975). The description theory showed how *a priori* knowledge would be possible, but doubts about such knowledge undermines the descriptive theory itself.

Descriptive theories made the mistake of tying what we mean exclusively to the general characterizations we associate with a term while ignoring what we have actually applied the term to (its 'putative extension'). This would suggest another approach to meaning, one that tied a term's meaning more closely to its putative extension. Such accounts can have antiskeptical consequences as well, but unlike descriptive theories, which seem better suited to underwrite *a priori* knowledge, such accounts underwrite perceptual knowledge.

Tying what a term means to its putative extension (or at least some privileged subset of it) is characteristic of the 'externalist' conceptions of meaning, which replaced the description theories in the 1970s (Kripke, 1972; Putnam, 1975). Such theories were often taken to rule out global skepticism about the external world, since if past usage determined what we meant by a term, then it made no sense to say that we might have always *mis*applied it. If, for instance, we were all brains in vats, and our 'perceptions' had always been determined by a supercomputer we were connected to, then our beliefs and assertions about the 'pens' around us would still be true, since by 'pen' we would mean the *virtual* pens that caused our pen utterances, not the 'real' pens that we hadn't had any contact with (Putnam, 1981). The externalist needn't rule out the kind of scenario that the skeptic traditionally relies on; she just denies that in such a scenario our beliefs would be false.

However, as an antidote to skepticism, such simple versions of externalism face two problems. First of all, even if externalism seems to secure the general veridicality of our beliefs, it does so at the expense of making our knowledge of our own thoughts problematic. After all, if the content of our beliefs is determined by such 'external' factors such as the nature of those items in our environment that we have *actually* applied it to in the past, and we don't have introspective access to such factors, then we may seem to lack introspective access to the content of our own beliefs (McKinsey, 1991; Falvey and Owens, 1994). We may have true beliefs, but our ignorance of their content prevents us from having knowledge. Second, it does seem possible that all of our applications of a term

could be misapplications. For instance, there have been many witch sightings throughout history, and since there are no witches, we can assume that all these perceptually based witch beliefs were false. Our general characterization of 'witch' was not satisfied by any of the people who were called 'witches.' The fact that the meanings of our terms could be affected by these general characterizations makes the transition from externalism to antiskepticism about perceptual judgments problematic. (The same problem emerged with the earlier 'paradigm case' arguments, which also made an attempt to equate a term's meaning with 'uncontroversial' cases of what we actually applied it to.)

The problems with these two sorts of account suggest that one's account of meaning should involve *both* a term's putative extension and the general characterizations associated with it. Something like this combination is found in Davidson's tying meaning to all of the sentences we take to be true, where this class includes both our general beliefs and our dispositions to apply terms to various objects in our actual environment. Davidson insists that on such a holistic account, we must treat a term's meaning as being that which would make *most* of the commitments associated with it true, so his view can still be understood as having antiskeptical consequences (Davidson, 2002). It might be that most of our beliefs about pens were false (because they weren't true of what we actually applied the term to), or it might be that most of the things we called 'pens' weren't pens (because they didn't satisfy most of our central 'pen beliefs'), but it couldn't be the case that *both* sorts of mistakes were the norm.

Still, even if most of our commitments turn out to be true on such an account, there will be no way to tell *a priori* which these will be. The holistic nature of the dynamic between our terms' putative extensions and general characterizations may insure that if our terms pick out anything at all, then the most deeply entrenched elements of our usage will turn out to be correct, but there is no guarantee that any *particular* aspect of a term's putative extension or general characterization will be among the set that ultimately reflects what we mean. Further, the fact that worries about our semantic self-knowledge remain on such an account, and that we can't be sure of the truth of any *particular* belief, suggests again that what the holistic theory gives us is a confidence that most of our beliefs must be true, not knowledge of any particular set of propositions.

It seems, then, that neither analyses of particular epistemic terms such as 'know' nor general semantic theories ruling out widespread misrepresentation can completely put skeptical worries to rest. This may be fortunate, since such strong antiskeptical consequences can be viewed as a sign that a semantic theory treats our representational capacities as *too* constrained and that a more expansive notion of what contributes to meaning is needed (Nagel, 1986).

Equatorial Guinea: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Equatorial Guinea is one of the smaller African countries, with an area of about 28 000 sq km and a population of just under 0.5 million people. Its language situation, however, is comparatively complex, like that of many neighboring African countries. Geographically, Equatorial Guinea is divided into a mainland part (Riu Muni), bordering Cameroon in the north and Gabon in the east and south, and several islands, the most important of which is Bioko Island (formerly Fernando Po), on which the capital of Malabo is situated. Equatorial Guinea was a Spanish colony for almost 200 years, until independence in 1968. Although for a long time it was among the poorer countries of the world, Equatorial Guinea's economy has seen tremendous growth rates since the first revenues from the newly established oil industry in 1996. It remains to be seen if the increased income will benefit the country at large.

The main languages of Equatorial Guinea are the Bantu languages Fang, a major language of the mainland, and Bube, of Bioko Island. Smaller Bantu languages spoken mainly on the coastal strip of the mainland and adjacent islands include Batanga, Benga, Ngumba, Ngumbi, Seki, Yasa, and Gyele. Spanish, the official language, is an important language in government, administration, the media, and education. French and West African Pidgin English (also called Weskos) play an important role as lingua francas in urban areas, due to comparatively large communities from neighboring West African countries, especially Nigeria and Cameroon. Two creole languages are spoken in Equatorial Guinea; Fernando Po Creole English, an English-based creole, similar to Krio, which is found mainly in the northern part of Bioko Island near Malabo, and Fa D'Ambu (or Annobonese), a Portguese-based creole spoken on the southern island of Annobón and by the Annobonese community on the island of Bioko. Fa D'Ambu originated on the then Portuguese island of Annobón as a pidgin language of speakers from different parts of the Portuguese colonies Angola and São Tomé who had been brought to Annobón as part of the Portuguese slave trade. Fa D'Ambu enjoys comparatively high prestige amongs its speakers and is used in many communication domains.

Spanish is the dominant language used in administration, education, and media. There are some eight radio stations and one state-owned TV station that broadcast mainly in Spanish, with some programs in other languages. Education at the primary and secondary levels is provided in Spanish. The literacy rate is around 70%.

The term 'ergativity' is used to refer to phenomena in which the subject of an intransitive verb is treated the same as the object of a transitive verb, in situations where the subject of a transitive verb is treated differently. This contrasts with languages like English, in which the subject of an intransitive verb is treated the same as the subject of a transitive verb. The phenomenon of ergativity was first noted and is most common and clear when it appears in morphological marking, so let us begin with a morphological example. Contrast Latin morphology, in which the intransitive subject of (1a) has the same nominative case as the transitive subject of (1b), but the intransitive object is marked differently, in accusative case, with

Inuit (Greenlandic Inuktitut) morphology, in which the intransitive subject of (2a) is marked in the same absolutive case as the object of the transitive sentence in (2b) and the transitive subject of (2a) is given a different, ergative case marking. One can also observe the Latin morphological pattern in English pronouns (*She comes/She hears him*), but in English, morphological marking is restricted to pronouns.

(1a) puella veni-t
girl.NOM *come*-PRES.IND.3SG
'the girl comes'

(1b) puer puella-m audi-t
boy.NOM *girl*-ACC *hear*-PRES.IND.3SG
'the boy hears the girl'

(2a) Oli sinip-poq
Oli.ABS *sleep*-IND.INTR.3SG
'Oli sleeps'

(2b) Oli-p neqi neri-vaa
Oli-ERG *meat*.ABS *eat*-INDIC.TRANS.3SG.3SG
'Oli eats meat'

Geographical and Linguistic Distribution of Ergative Languages

Ergative morphology at first seems rather strange and unnatural to those with a background in traditional grammar and the major European languages. However, it is not at all uncommon; around one-quarter to one-third of languages have ergativity (to varying extents). Ergativity is unevenly distributed geographically. It is particularly common among Australian, South American, Caucasian, Asian, and Pacific languages. In some sense, the best known ergative languages are perhaps Basque and Inuit. The ergative language with the most speakers is Hindi. Mayan languages are also mainly ergative. The uneven geographic distribution of ergative languages is to be expected, given that many languages are related as part of larger language families, which usually occur over a contiguous geographic area. However, it is important to note that many language families contain both ergative and accusative languages. The Indo-European language family includes many languages exhibiting ergativity in the Indo-Iranian part of the family tree. Conversely, Australian languages are mostly morphologically ergative, but there are some subgroups with accusative morphology, particularly the Mantharta subgroup from northwest Western Australia (Dench, 1982).

Ergative Argument Marking (Morphological Ergativity)

It makes good communicative sense that languages should have a basic coding method to differentiate the two arguments of a transitive verb. Although it is unnecessary for some verbs, such as with *The man cooked beans*, there are many predicates such as *The man saw the lion,* in which this disambiguation is important. Indeed, all languages do this, using three mechanisms: (1) changing the form of words of the dependent argument, that is, by case-marking morphology; (2) putting agreement markers on the head predicate; or (3) using the ordering of the arguments. This does not mean that the result is always unambiguous, though; there are some cases in which ambiguity remains because either case markers show syncretism across cases or agreement markers do not differentiate arguments of the same person, number, and gender. But in general these mechanisms allow us to distinguish the meanings of examples (1b) above versus (3).

(3) puer-um puella audi-t
boy-ACC *girl*.NOM *hear*-PRES.INDIC.3SG
'the girl hears the boy'

Use of standard grammatical terminology can become confusing or even misleading in the context of ergative languages because sometimes people use terms like 'subject' thinking of a subject's role as the main syntactic element in a clause and sometimes thinking from a more semantic vantage point, seeing the subject as indicating the most agentive argument. Here it is assumed that a predicate has an argument structure that gives the semantic roles of the predicate's arguments, and that these are divided into core arguments, which are normally mapped onto the surface subject and any objects (including possibly agentive complements in ergative languages), and oblique arguments, which are typically marked by oblique case markers or prepositions. This article will use the abbreviations A, S, and O to refer unambiguously to core arguments of a clause at the level of argument structure (following the notation of Dixon (1994), the standard reference text on ergativity). S is the single argument of an intransitive verb, and A and O are the two core arguments of a transitive verb. The more agent-like argument (or 'proto-agent,' in the terminology of Dowty, 1991) is denoted A, and the more 'undergoer'-like argument (or 'proto-patient') is denoted O. I will then use the term 'subject' exclusively to refer to the syntactically most prominent grammatical argument relation in a clause (Dixon, 1994, refers to this notion as the 'pivot').

Theories of case marking in turn standardly distinguish the main grammatical or structural cases, which mark the core arguments of intransitive and transitive verbs, regardless of their semantic role, from oblique cases, which are more semantically transparent in

meaning. The majority of languages with case marking have at least two structural cases, one used for the A and S arguments and the other for O arguments. These cases are termed 'nominative' and 'accusative.' Normally the accusative case is the marked case, as in the Latin examples 1a and 1b, and so we refer to such languages as accusative. By extension, any phenomenon that groups together S and A in opposition to O is also referred to as accusative. In the alternative organization, shown for Inuit in examples 2a and 2b, there are still two cases. Most linguists accept that they are still both structural cases (although some have argued for an analysis of ergativity whereby ergative languages have only one structural case and the ergative case is a semantic case). But in this case, the structural cases group S and O in opposition to A. This time, the case used to mark S and O is called 'absolutive,' and the case used to mark A is called ergative. As in the Inuit example, it is the ergative case that is the marked case, and so such languages are termed ergative, and by extension, any phenomenon that groups S and O in opposition to A is termed ergative.

Concerns of disambiguation motivate a system that differentiates A and O, but the remaining question is how to mark the single argument of an intransitive verb. One choice would be to mark it in a third way. There are occasional instances of such tripartite systems, but they are extremely rare and perhaps best thought of as a fairly unstable diachronic stage. A second choice would be to mark agent-like arguments of intransitive verbs like A arguments and patient-like arguments of intransitive verbs like S arguments. Such a 'split S,' or 'active-stative,' system is rather more common and occurs in various languages around the world, particularly North American and Caucasian languages – including some languages that are usually referred to as ergative (Mithun, 1991). For instance, it can be found in Basque (Hualde and Ortiz de Urbina, 2003):

(4a)	Jon	etorri	da
	Jon.ABS	*come:PTCP.PRF*	*is.3SG.INTR*
	'Jon came'		
(4b)	Jon-ek	saltatu	du
	Jon-ERG	*jump.PTCP.PRF*	*have.3SG.TR*
	'Jon jumped'		
(4c)	Jon-ek	ardo-a	ekarri
	Jon-ERG	*wine-DET.ABS*	*bring.PTCP.PRF*
	du		
	have.3SG.TR		
	'Jon brought the wine'		

Such active-stative marking may either be 'lexicalized,' whereby certain intransitive verbs select for a particular case, or it may be 'fluid,' with the choice of case marking indicating the perceived agentivity or volitionality of the action. It should be noted that for many languages with active-stative marking, either fluid marking or one choice of intransitive subject marker occurs only with a very restricted set of verbs, and so the languages have an overwhelmingly accusative or ergative character, and this restricted set of verbs might be considered exceptional. Such is the case for Basque.

The common situation across languages is that the S argument of intransitives is encoded uniformly like either the A or O argument of transitives, regardless of the verb's meaning, and this gives us the accusative and ergative case marking patterns with which we began in examples 1 and 2. These two case-marking choices can be illustrated graphically as follows:

(5)

In this diagram, there is no particular reason to choose one system or the other. Using either is sometimes natural and sometimes does violence to the semantics because one is either using a basically agentive marker sometimes for undergoer S arguments or else sometimes using a marker usually used for undergoers for an agent-like S argument. Nevertheless, a desire for economy in surface forms of expression appears to lead most languages to use one or the other strategy. Moreover, while the above diagram makes the two methods of marking entirely symmetric, the discussion of split ergativity below shows that this apparently symmetrical picture is actually somewhat misleading.

Ergative case marking is by far the most common strategy for ergative core argument marking, and we have already illustrated it in example 2. In the vast majority of ergative languages, the absolutive case is a bare stem with no overt case marker, and the ergative case is an overt case marker. In other respects too, the absolutive appears to be unmarked, and the ergative is a marked case. A common analysis is thus to unify absolutive and nominative as a single unmarked nominative case and then to view accusative and ergative as marked case forms.

A more modest number of languages have an ergative verbal cross-referencing system. Sometimes there is something more like participial agreement information (number and gender) on the verb agreeing with the absolutive (as in Hindi), but for other languages, like the Papuan language Yimas (Foley,

1991) or Mayan languages, there is an ergative cross-referencing system (S and O are marked the same in an agreement slot that precedes the A agreement slot):

(6a) pu-tmuk-t
3PL-fall-PERF
'they fell down'

(6b) pu-ka-tay
3PL-1SG-see
'I saw them'

(6c) na-mpu-tay
3SG-3PL-see
'they saw him'

Finally, there is extremely little evidence of languages showing ergativity only by word order (unlike the case for accusative languages), but there are cases in which the word order is ergatively patterned in line with another marking system, for instance Päri (Andersen, 1988):

(7a) ùbúr á-túuk`
Ubur PERF-play
'Ubur played'

(7b) jòobì á-kèel ùbúrrì
buffalo.ABS PERF-shoot Ubur-ERG
'Ubur shot the buffalo'

Syntactic Ergativity

The different morphological marking of ergative languages might suggest a very different syntactic organization at work, and this was certainly assumed by many early grammarians encountering ergative languages. Anderson (1976) questioned this, suggesting that languages with ergative morphology actually have the same syntactic organization as languages with accusative morphology. As an example of this, the Basque examples below from Ortiz de Urbina (1989) show how an absolutive reciprocal can be bound by an ergative noun phrase (NP) (8a), while the reverse is impossible (8b). Reciprocals never appear in the A or S subject positions, but an S can also bind an oblique reciprocal (8c):

(8a) Gudari-ek elkar hiltzen zuten
soldiers-ERG RECIP.ABS kill AUX
'the soldiers$_i$ killed each other$_i$'

(8b) *Gudari-ak elkarr-ek hiltzen zituen/ zituzten
soldiers-ABS RECIP-ERG kill AUX
'theyselves$_i$ killed the soldiers$_i$'

(8c) Lagun-ak elkarr-ekin joan dira
friend-ABS RECIP-with go AUX
'the friends$_i$ have gone with each other$_i$ (i.e., together)'

This analysis indeed appears to be true for many languages with ergative morphology. However, it has now been comprehensively established that a subset of ergative languages show an ergative organization in their syntax (to varying extents) as well. The most famous examples are certain north-eastern Australian languages such as Dyirbal (Dixon, 1972). Among other evidence, we find that clause linking (processes of reduction in clause coordination) patterns ergatively. The two clauses have to share an S/O NP:

(9a) bayi yara baŋgul gubi-ŋgu
this.ABS man.ABS this.ERG gubi-ERG
munda-n baŋgun jugumbi-ru balga-n
bring-NFUT this.ERG woman-ERG hit-NFUT
'the gubi [shaman] brought the man here and the woman hit (him)'

(9b) bayi Burrbula baŋgul gubi-ŋgu
this.ABS Burrbula.ABS this.ERG gubi-ERG
bara-n baji-gu
punch-NFUT fall.down-PURP
'the gubi punched Burrbula$_i$ and [he$_i$] fell down'}

Many (although not all) syntactically accusative languages have a passive verb form, used to demote an agent to an oblique, a process that can then feed syntactic operations like clause chaining (as in *I came and was seen by Bill*). Conversely, a good number of ergative languages have an antipassive verb form, used to demote an absolutive to an oblique case, intransitivizing the verb. In the example below, the antipassive demotes the O argument of *see* to being a dative oblique so that clause chaining can occur between two intransitive clauses:

(10) ŋana banaga-ɲu bural-ŋa-ɲu
we.NOM return-NFUT see-ANTIPASS-PURP
ɲura-ŋgu
you-DAT
'we returned and saw you'

However, this is not the full story. Antipassives occur quite commonly in ergative languages regardless of whether they are only morphologically or syntactically ergative, and some ergative languages have both a passive and an antipassive. An example is Inuit, as in the examples below from Bittner (1994). Going in the opposite direction, there do not appear to be cases of a general antipassive construction in languages with accusative morphology and syntax, although there are occasional more limited processes with similar effect (such as *unspecified object deletion* in English, which gives *I ate* from the transitive verb *eat*).

(11a) Juuna-p miiqqa-t
Juuna-ERG children-PL.ABS
paar-ai
look.after-IND.TR.3SG.3PL
'Juuna is looking after the children'

(11b) miiqqa-t Juuna-mit
child-PL.ABS *Juuna*-ABL
paari-niqar-put
look.after-PASS-IND.INTR.3PL
'the children are looked after by Juuna'

(11c) Juuna miiqqa-nik
Junna.ABS *child*-PL.MOD
paari-si-vuq
look.after-ANTIPASS-IND.INTR.3SG
'Juuna is looking after children'

In almost all theories of syntax, there are notions corresponding to subject and object as surface grammatical relations, regardless of whether they are primitives of the theory or defined configurationally in terms of phrase structure positions. The question then is how to map syntactic ergativity onto surface grammatical relations. There are a number of conceivable answers to this conundrum, all of which have been proposed by some linguists. Possible approaches are given in (12).

(12)

a	Subject	A, S	Syntactic accusativity
	Object	O	
b	Oblique agent	A	Oblique ergative analysis
	Subject	S, O	
c	Subject	A	Absolutive-S as object
	Object	S, O	
d	Subject	A	Ergative Four relations analysis
	Object	S, O	Absolutive
e	Object	A	Inverse analysis
	Subject	S, O	

Approach 12a gives the language an analysis like an accusative language. This appears to be the right analysis for languages with only morphological ergativity, such as Warlpiri or Basque, but does not explain the appearance of ergative syntactic constructions of the sort we have just discussed. The approach shown in 12b treats the ergative as an oblique rather than a core argument of the sentence. This is also the claim of an ergative-as-passive analysis, which says that syntactic ergativity is the result of covert passivization. The two analyses differ only in terms of mechanism. Such an analysis says that syntactically ergative languages have only intransitive sentences and that ergative is an oblique case. This analysis does not appear to be correct. There are good arguments from languages that show syntactic ergativity, such as Dyirbal and Inuit, that clauses with an ergative NP are transitive (Manning, 1996). For instance, this seems the only way to understand valency-changing operations, such as the Dyirbal applicative, or the presence of nominative-accusative morphology on pronouns in the language. Approach 12c treats the absolutive S as an object, and so sentences with an S are in some sense intransitive but subjectless. This analysis has some appeal but fails to capture that the absolutive NPs in syntactically ergative languages have classic subject properties for phenomena like clause chaining, as we observed above. The four-relations analysis makes all four putative grammatical relations available in every language. It is harder to prove such an analysis wrong, but besides transgressing on the count of general permissiveness, it does not by itself predict the restrictive patterns of mixed syntactic behavior that are found in languages, which we turn to below. The inverse analysis treats the S and O as the grammatical subject in syntactically ergative languages, while the A is analyzed as an object (or an agentive complement, if one frowns on viewing a semantic agent as an object). This analysis naturally explains the surface syntactic patterning of ergative languages, such as the Dyirbal clause-chaining facts shown in example 10, and is the analysis adopted in Manning (1996). However, more needs to be said to explain the rather mixed character of many syntactically ergative languages, and this topic is taken up in the next section.

An alternative analysis is to suggest that, while there is an inversion whereby the absolutive argument has a certain sort of prominence in syntactically ergative languages, this does not happen at the level of grammatical relations (that is, an analysis of syntactic accusativity is assumed) but rather at the level of interclausal organization or discourse (Du Bois, 1987).

Split Ergativity

There is an asymmetry in linguistic systems in that while many languages appear to be entirely accusative in terms of their case marking, agreement, and

syntactic systems, there do not appear to be any languages that pattern entirely ergatively. Many languages have a largely ergative nature, but there always seem to be some traces of accusative organization, while yet other languages show quite a mix of ergative and accusative characteristics. The split between ergative and accusative patterning can be organized along a number of dimensions, and it can span both morphology and syntax.

Splits in Case Marking

Beginning first with morphology, in general languages with ergative case marking patterns are actually split between ergative and accusative. There is a continuum; some use nearly entirely ergative case marking, whereas in others ergativity is much more limited. A dimension of variation is what conditions the split. Various Indic languages, such as Hindi, are well known for having split ergative case marking in which ergativity appears only in the perfect aspect. A tense- or aspect-conditioned split is also found in some other languages, such as Burushaski. Some Urdu examples from Butt (1995) are shown here:

(13a) Naadyaa xat lik^{h}-tii
Nadya(FEM) *letter*(MASC) *write*-IMPF.F.SG
hai
be.PRES.3SG
'Nadya writes a letter'

(13b) Naadyaa-ne xat lik^{h}-aa
Nadya(FEM)-ERG *letter*(MASC) *write*-PERF.MASC.SG
hai.
be.PRES.3SG
'Nadya has written a letter'

(13c) Naadyaa-ne ciṭṭ^{h}ii lik^{h}-ii
Nadya(FEM)-ERG NOTE (FEM) *write*-PERF.FEM.SG
hai
be.PRES.3SG
'Nadya has written a note'

Note the change of verbal agreement as well as the case marking (in general, Hindi verbs agree only with nominative arguments).

Perhaps the most common, and certainly the most discussed, kind of split-ergative case marking occurs when some noun classes are marked ergatively and others accusatively. The splits that usually occur have an interesting patterning, which is captured in the Silverstein Hierarchy (Silverstein, 1976):

(14) The Silverstein Nominal Hierarchy
1st and 2nd person pronouns > 3rd person pronouns/demonstratives > Proper nouns > Animate nouns > Inanimate nouns

The general functional pressure underlying this hierarchy is that things at the left end of the hierarchy are more likely to be an actor that serves as the A role, while things at the right end are more likely to be acted on and fill the O role. To the extent that case marking serves to mark nonstandard configurations but an unmarked absolutive/nominative marks the default role of an NP, it makes sense to mark things at the right end, when they are serving as A, by an ergative case and things at the left end, when they are serving as O, by an accusative case. Many languages do this. For example, in Dyirbal, just first- and second-person pronouns have nominative/accusative marking; all other nominals are ergatively marked (Dixon, 1994):

(15a) ŋana banaga-ɲu
we.NOM *return*-NONFUT
'we returned'

(15b) ɲurra banaga-ɲu
you.PL.NOM *return*-NONFUT
'you all returned'

(15c) ɲurra ŋana-na bura-n
you.PL.NOM *we*-ACC *see*-NONFUT
'you all saw us'

(15d) ŋuma yabu-ŋgu bura-n
father.ABS *mother*-ERG *see*-NONFUT
'Mother saw Father'

Note that this morphological split does not have ramifications for the syntax of Dyirbal; phenomena like clause chaining behave the same regardless of the morphology, as was partially illustrated in (10) above. This independence of morphology and syntax appears to be the norm across ergative languages, regardless of whether they have ergative or accusative syntax.

Things do not always work out quite as simply as the Silverstein Hierarchy suggests. Sometimes the ranges of ergative and accusative marking overlap, and there is tripartite marking in the middle of the scale; sometimes the facts are complicated by certain case markings being present in particular noun classes at a more fine-grained level than the hierarchy above can capture. But the hierarchy is nevertheless a useful typological starting point.

Split between Case Marking and Agreement

Another very common form of split is between nominal case marking and verbal coreferencing. Here, the standard pattern is that nouns show ergative case marking, but the verbal coreferencing is accusative. This is illustrated by the Australian language Warlpiri in the examples below. Nouns (including pronouns) show ergative case marking, but verbal agreement on the auxiliary cross-references core arguments on an accusative pattern.

(16a) Ngaju ka-rna wangka-mi
I.ABS AUX.PRES-*1*SG *speak*-NONPAST
'I am speaking'

(16b) Ngajulu-rlu ka-rna-ngku nyuntu
I-ERG AUX.PRES-*1*SG-*2* *you*.ABS
nya-nyi
see-NONPAST
'I see you'

There do not appear to be languages that exhibit the opposite split of having uniform accusative morphology but ergative verbal agreement.

Splits in Syntactic Behavior

The traditional basis for identifying syntactic ergativity is to use phenomena that linguists have seen as associated with the subject of a sentence, then to see whether a phenomenon exists in a certain language, and then whether it applies to only S and A noun phrases or only S and O noun phrases. On this basis, Dyirbal has been the canonical case of a language with strongly ergative syntax. However, even in Dyirbal, it is not the case that all subject properties fall to the absolutive NP. For instance, the role of being the addressee of an imperative certainly groups S and A. Dyirbal perhaps only looks more ergative than some other languages because some other properties that typically behave syntactically accusatively in languages are not applicable tests in Dyirbal. For example, reflexive binding is done by a detransitivizing verb form. Although there are some analytically difficult cases, most languages with syntactic ergativity seem to show a fairly consistent split in terms of which syntactic tests show syntactic ergativity and which do not, as in Table 1.

For example, we can contrast in Inuit the fact that only S and O arguments can be relativized on in Inuit (participial) relatives, as in 17a through 17c, while only S and A arguments can control reflexives, as in 18a through 18c:

(17a) nanuq Piita-p tuqu-ta-a
polar.bear *Piita*-ERG *kill*-TR.PART-*3*SG
'a polar bear killed by Piita'

(17b) miiraq kamat-tu-q
child.ABS *angry*-REL.INTR-SG
'the child that is angry'

(17c) *angut aallaat tigu-sima-sa-a
man.ABS *gun*.ABS *take*-PRF-REL.TR-*3*SG.*3*SG
*'the man who took the gun'

(18a) ataata-ni Juuna-p tatig-aa
father-*4*SG.ABS *Juuna*-ERG *trust*-IND.TR.*3*SG.*3*SG
'Juuna$_i$ trusts his$_i$ father'

(18b) Aani illu-mi-nut ingerla-voq
Anne.ABS *house*-*4*SG-TERM *go*-IND.INTR.*3*SG
'Anne$_i$ is going to her$_i$ house'

(18c) *Anaana-mi Piita nagligi-jaŋa
mother-*4*SG.ERG *Piita*.ABS *love*-*3*SG.*3*SG
*'His$_i$ mother loves Piita$_i$'

Manning (1996) proposes that the way to explain this split is to argue that the S and O NPs fill the grammatical relation subject in syntactically ergative languages, but that the A and O arguments remain the most prominent argument at the level of argument structure, and then to adopt an analysis in which phenomena like control and reflexive binding are sensitive to argument structure rather than to surface syntax (Culicover and Jackendoff, 2005). An advantage of such an analysis is that it suggests a promising extension to the treatment of Philippine languages (and Austronesian languages more generally). Philippine languages have commonly been seen as a rather special third class of languages, fitting neither the syntactically ergative nor the accusative mold, and with a famous split in subject properties (Schachter, 1976). But, given that syntactically ergative languages exhibit much the same split of subject properties, the two classes can be folded together. Philippine languages are then special only in allowing a greater range of semantic roles to serve as syntactic subject than most languages, whereas other Austronesian languages, such as Balinese (Bali), have a more conventional syntactically ergative appearance (Wechsler and Arka, 1998).

Historical Change

Ergativity splits almost necessarily seem somewhat messy from the viewpoint of theoretical syntax, whereas a neater analysis would result from uniform behavior. But split behavior is well motivated functionally: both the A=S and O=S identification have a strong semantic basis, and it makes particular sense to make the former identification with prototypical agents (pronouns or all animate nouns) and the latter identification with prototypical undergoers (inanimate nouns). Split ergativity can also be viewed historically as an intermediate point in a historical evolution. Languages are not statically ergative or accusative. There are fairly well examined cases of languages changing their character from ergative to accusative and vice versa. There

Table 1 Syntactic phenomena typically showing ergative versus accusative behavior

Ergative S=O grouping	*Accusative S=A grouping*
Shared argument in coordination	Addressee of imperative
Obligatory element in clause	Binder of reflexive pronouns
Raised argument	Controlled argument in controlled clauses
Pivot for relativization	Used in switch-reference systems
Wide scope or definiteness needed	

is also a fairly intuitive account of how this can happen, dating to at least Kuryłowicz (1946). The basic observation is that if an accusative language has a passive (that allows expression of an oblique agent) and, for whatever reasons, prefers passive verb forms to the point that it stops using transitive verb forms (as seems to happen in various languages, such as the Polynesian language Maori), then the language has almost become ergative. This transition is complete when the previous marker of an oblique agent is reinterpreted as the marker of a core grammatical relation, and the old passive marker is reanalyzed (perhaps as a transitive marker). The same account can be told in reverse for an ergative language that prefers the antipassive, becoming accusative. From what we know from incomplete historical records, both of these pathways of change do seem to occur. But this is not the only means by which ergativity can arise or be lost. Another particularly common pathway for languages to become ergative is through reanalysis of nominalizations, frequently those involving passive participles. This pathway seems to be the historical basis in a number of language families (for example, Inuit, Mayan, and Austronesian languages) for using the same case form for both the genitive and the ergative case.

Final Remarks

Dixon (1994) is the first place that readers should look for a more comprehensive study of ergativity. Plank (1979) is an important earlier collection. There has been much theoretical literature on the treatment of ergative languages. For case marking, important recent approaches include Bittner and Hale (1996) and Woolford (1997), while for syntax, Bittner (1994) and Manning (1996) present detailed studies.

The term 'ergative' has also been used by some authors to refer to lexical semantic alternations in which a verb appears both transitively and intransitively, with the object of the transitive use having the same undergoer semantic role (theme/patient) as the subject of the intransitive use (such as for the verb *broke: The boy broke the mirror/the mirror broke*). Either the subject of the transitive may be referred to as ergative, or the intransitive form may be referred to as an ergative verb. These extensions of the term are generally seen as confusing by typological linguists; the intransitive form of such verbs is probably better referred to as 'unaccusative.'

Eritrea: Language Situation

D Appleyard, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

There are nine languages spoken in Eritrea in addition to English and Italian, the former colonial language. The major language of the country is Tigrinya, spoken by about 2 million people or 50% of the population as a first language. Tigrinya is also spoken in northern Ethiopia. The other Eritrean languages are Tigre, a sister Ethiopian Semitic language of Tigrinya, with 990 000 speakers (approximately 25% of the population), the Cushitic languages Afar (Qafar) with between 160 000 and 300 000 speakers, Saho with about 150 000, Beja (Bedawi) with between 80 000 and 120 000, Bilin with 70 000, and two Nilo-Saharan languages, Kunama with approximately 64 000 speakers and Nara with 48 000. In addition to these, a variety of Hijazi Arabic usually called Rashaida in the Eritrean context has also been spoken by a small population in Eritrea at least since the 19th century. A possible tenth indigenous language is Dahlik, with about 2000 speakers on the Dahlak islands, if this is not simply a divergent dialect of Tigre. The working languages within the country are Tigrinya and Arabic, which owes its particular status to the high percentage of Muslim Eritreans and to Eritrea's relations with neighboring Arabic-speaking states.

Aside from being the first language of about half the population of Eritrea, Tigrinya is also closely associated with the Christian religion and the Orthodox Church, where it has in some degree replaced Ge'ez as the liturgical language. English was the official language of the state, and it still remains the language of much international communication.

Since Eritrea gained full independence from Ethiopia in 1993, a concerted program of developing Eritrea's nine indigenous languages toward literacy and inclusion in education and the media has been pursued. Popular preference, however, has not always followed the same lines, as for instance with the Afar who have elected to have their children educated through the medium of Arabic. Aside from Arabic of course, only Tigrinya has any history of being a written language, with the first attestations right at the end of the 19th century. As part of the then Ethiopian kingdom, there had been a long tradition of literacy in Ge'ez (Classical Ethiopic) within the heritage and culture of the Ethiopian Orthodox Church. Tigrinya has always been written in a slightly expanded version of the Ethiopic syllabary, used for Ge'ez, and the same script is also being used for Tigre, Eritrea's other Semitic language, while Latin scripts have been developed for the non-Semitic languages, though the Ethiopic syllabary was also used for Bilin, especially among the expatriate community. However, there has been some preference for using the Arabic script by Muslim communities. Literacy is at present estimated at about 58%.

Eritrea's two Semitic languages, Tigrinya and Tigre, both belong to the northern branch of the Ethiopian Semitic group, as does the ancient Ge'ez language, now used only in liturgical contexts, especially in Ethiopia. Afar and Saho are closely related Lowland East Cushitic languages, of which they together form a single branch, while Beja, which also is spoken in the Sudan, itself forms a distinct branch of the Cushitic family, and Bilin belongs to the Central Cushitic or Agaw division of the family, the other members of which are all spoken in Ethiopia. The classification of the two Nilo-Saharan languages is somewhat more problematic, though it is generally agreed that Kunama itself forms a separate branch, while Nara is a member of the Eastern Sudanic group.

Eskimo–Aleut

A Berge, University of Alaska, Fairbanks, AK, USA

© 2006 Elsevier Ltd. All rights reserved.

The Terms 'Eskimo' and 'Aleut'

The terms 'Eskimo' and 'Aleut' have unclear origins. 'Eskimo' is commonly believed to be derived from a derogatory Algonquian term meaning 'eaters of raw meat'; it has been replaced with Inuit, meaning 'people,' in most of Canada, and the language is referred to variously as Inuinnaqtun, Inuttun, Inuktitut, and by other names. The term 'Aleut,' confusingly, was bestowed on Aleut and Yupik people native to the Aleutian Islands and part of the southwestern Alaskan mainland, as well as on their languages, by Russians in the 18th century. The term in use in Alaska today for self-designation of the non-Yupik Aleut is Unangan or Unangas for the people and Unangam Tunuu for the language; however, the term 'Aleut' is preferred in Russia. Because there is still no other general term to describe all of the languages and dialects encompassed by the terms 'Eskimo' and 'Aleut,' and for reasons of linguistic tradition, they are still commonly used within the field of Eskimo–Aleut linguistics.

History and Genetic Relationships

The Eskimo–Aleut language family is spoken from the Siberian coast in the west to Greenland in the east. There are two major branches, Aleut and Eskimo, and Eskimo consists of at least two further subgroups, Yupik and Inuit. One recently extinct language, Sirenikski (Sirenik Yupik), may either have been a third branch of Eskimo or one of the Yupik languages.

The Eskimo and Aleut people are thought to have been part of the last large-scale migration from Asia across the Bering land bridge, between 4000 and 6000 years ago. Various attempts have been made to link Eskimo–Aleut with other language families on the Asian continent (e.g., Uhlenbeck, 1935, Swadesh, 1962). While there is little solid linguistic evidence of a genetic relationship between Eskimo–Aleut and other language families, there are strong suggestions of very early contact, particularly with Uralic (for a discussion of possible linguistic affinities and contact, see Fortescue, 1998). The development and differentiation of the Aleut and Eskimo languages and dialects probably took place in Alaska because of the linguistic diversity found on the Alaskan side.

From Alaska, there were several waves of migration down to the Aleutians, west again to Siberia, and eastward to Greenland. The earliest led to the linguistic split between Aleut and Eskimo, possibly around 4000 years ago, although there is archeological and skeletal evidence to suggest an earlier physical divergence (Laughlin, 1980). The earliest Aleut settlements appear to have been around the Island of Four Mountains, whence there were eastward and westward migrations. The Yupik and Inuit branches of Eskimo must have diverged about 2000 years ago. From their homeland around the Seward Peninsula, Yupik speakers occupied southwestern Alaska and, moving westward across the Bering Strait, reoccupied the Chukchi Peninsula in Siberia. If Sirenikski is a separate branch of Eskimo, then it may have split off about 2500 years ago and its origins may be on the Chukchi Peninsula as a result of an earlier back migration. It was gradually displaced by Central Siberian Yupik and neighboring Chukchi (Chukot). The ancestors of the Inuit spread northward and eastward in several waves. The latest migration began about 1000 years ago, and resulted in the rapid spread of the Inuit language, leaving few linguistic traces of previous Eskimo populations. The present dialect differentiation (see Figure 1) is possibly as recent as the past 500 years (see Dorais, 1996).

Historiography of Research

The first systematic linguistic studies of an Eskimo–Aleut language were made in Greenland, beginning in the 18th century. Outside of Greenland, most available materials on the Eskimo–Aleut languages consisted of word lists until well into the 19th century, and even into the 20th century for some of the western Inuit dialects (*see* **West Greenlandic** and **Inupiaq**). Nevertheless, the Danish scholar Rasmus Rask proposed a genetic relationship between Aleut and Eskimo languages as far back as 1819. His notes were published in 1916 (Thalbitzer, 1916), and his thesis was confirmed through Marsh and Swadesh (1951) and Bergsland (1951). More recently, comparative work has been done by Bergsland (1986, 1989) and Fortescue *et al*. (1994).

Linguistic Characteristics of Eskimo-Aleut

The following features are characteristic of the Eskimo-Aleut language family:

- There are three basic vowels (i, u, a), derived from an original four-vowel system (i, u, a, and schwa, represented by [e] in Yupik, which maintains the four-vowel distinction).

Figure 1 Eskimo-Aleut languages and major dialects. (Adapted from Map 1 in Fortescue *et al.* (1994)).

- Word building is almost exclusively through suffixation, the only exception being an anaphoric prefix *ta-* on demonstrative stems (e.g.,pan-Eskimo *una* (DEIC-PRX), *tauna* 'this one').
- To a greater or lesser degree within the language family, polysynthesis is the norm: very complex verb structures encode meanings for which other languages need whole sentences. This example is from Uummarmiut Eskimo (from Inuvik):

  kivgaluk-niaq-qati-gi-tqik-kuminait-kiga
  muskrat-hunt-partner-have.as-again-will.never-1SG.3SG.INDIC
  "I will never again have him as a partner to hunt muskrat" (Lowe, 1985: 18)

- Sentences typically consist of clause chains, in which a series of dependent clauses is headed by an independent clause. In the following simple example from West Greenlandic, there is one indicative clause and two subordinated participial clauses; clause chains can be quite extensive:

  irn-i qajartur-tuq
  son-his own be out in kayak-3SG.PART
  qinnguar-paa
  see through binoculars-3SG.3SG.INDIC
  natsirsu-up sursuk-kaa
  hooded seal attack-3sg.3sg.PART
  "he$_i$ saw his son$_j$ through his binoculars being attacked by a hooded seal while in his$_j$ kayak" (Fortescue, 1984: 39)

- Word order is typically SOV to a more or less fixed degree (Aleut has essentially fixed word order). In the previous example, the object clause *irni qajarturtuq* precedes the verb, and the subject of each of the subordinated clauses precedes its respective verb.
- Case marking follows the ergative-absolutive case-marking pattern (with extreme modifications in Aleut), where the subject of intransitive verbs receives the same marking as the object of transitive verbs, namely absolutive case, while the subject of transitive verbs receives a different marking, ergative case.

The Eskimo languages are much more closely related to each other than to Aleut. In addition to the common features listed for Eskimo–Aleut, they share

- certain restrictions on syllable and other phonological structures;
- up to six nongrammatical cases in addition to ergative and absolutive cases (locative, instrumental, ablative, allative, vialis, and equalis);
- transitive and antipassive structures, the choice of which appears to be partially determined by definiteness, as in the Central Alaskan Yup'ik (Central Yupik) examples below:

  angute-m neqa ner-aa
  man-ERG.SG fish-ABS.SG eat-3SG.3SG.INDIC
  'the man eats **the** fish'

  Angun neq-mek ner'-uq
  man-ABS.SG fish-INSTR.SG eat-3SG.INDIC
  'the man eats **a** fish'

Aleut

Aleut is a language with two major extant dialects, and at least two other dialects historically attested. Eastern Aleut is spoken east of Amukta Island to the Alaskan Peninsula, as well as on the Pribilof Islands. Atkan, also variously called Western or Central Aleut, is today spoken on Atka Island, and a version of it is spoken on Bering Island. A third dialect, Attuan, is essentially dead; a mixed language known as Copper Island Aleut (Mednyi Aleut), consisting of Attuan stems and Russian inflection, is still spoken on Bering Island. There is scant evidence in very early descriptions of a dialect spoken on the Rat Islands between Attu and Atka, suggesting a dialect continuum in the West.

Characteristic of Aleut are

- its lack of labial stops (although it appears that Copper Island Aleut has developed voiced labial stops), and its aspirated nasals;
- consonant clusters which differ from those in Eskimo in their distribution (e.g., they are permitted word initially, as in *qdinalix* 'to be slippery'), in the combinations of consonants possible (e.g., velar-uvular fricatives), and in their complexity (allowing up to three consonants, as in *chax̂sxix̂* 'reef');
- use of independent pronouns, as opposed to pronominal marking on verbs in Eskimo languages:

Aleut	txin	achix-ku-qing
	you	*teach*-PRES-1SG
		'I am teaching you'
Greenlandic		ilinniar-tip-pakkit
		learn-cause-1SG.2SG.INDIC
		'I am teaching you'

- its typologically unusual agreement system, in which ergative case marking is only used if a transitive object or an object of possession is not overtly expressed:

Piitra-x̂	tayaĝu-x̂	kidu-ku-x̂
Peter-ABS.SG	*man*-ABS.SG	*help*-PRES-3SG
'Peter is helping the man'		

Piitra-m	kidu-ku-u
Peter-ERG.SG	*help*-PRES-3SG.3SG
'Peter is helping him'	

Through contact with Russian traders and colonizers in the 18th and 19th centuries, modern Aleut has a large proportion of Russian loanwords. As a result of early decimation of the people and later suppression of the language in the schools, the language is severely endangered today, with at most 150 speakers in the Aleutian Islands, the Pribilof Islands, and Anchorage, and perhaps 10 on Bering Island. With the exception of Atkan, speakers are elderly.

Yupik

The Yupik languages include Naukanski (Naukan Yupik), spoken around East Cape on the Chukchi Peninsula; Central Siberian Yupik, spoken on the Chukchi Peninsula and on St Lawrence island; Central Alaskan Yup'ik, spoken from Norton Sound to Bristol Bay in Alaska; and Sugpiaq (Pacific Gulf Yupik), also known as Sugcestun or Alutiiq, spoken around Prince William Sound, the Alaskan Peninsula, Kodiak and Afognak Islands, and the tip of the Kenai Peninsula. Yupik languages are characterized by

- their retention of a fourth vowel that presumably stems from Proto-Eskimo (cf. Proto-Eskimo **neqe* became Central Alaskan Yup'ik *neqa* 'food,' Iñupiaq [North Alaskan Inupiatun] *niqi* 'food');
- more or less complex effects of intonational stress; in stressed syllables, for example, the vowel is often lengthened (for more on Yupik prosody, see Krauss, 1985).

There are some nonnegligible syntactic differences between the languages, although these have not yet been well described. Siberian Yupik languages have a number of English loan words, from contact with 19th-century whalers, and Alaskan Yupik languages have a large number of Russian loans from 18th- and 19th-century Russian colonization, as well as 20th-century English loans. Most Yupik languages are severely endangered today, with numbers of speakers ranging from 70 (Naukanski) to 1300 (Central Siberian Yupik). The notable exception is Central Alaskan Yup'ik, with about 10 000 speakers (and on the Kenai Peninsula these include children), and with immersion programs in the schools and active production of learning materials.

Sirenikski

Sirenikski is seen as an important link to Proto-Eskimo because of particularly conservative features, such as a retention of consonants between vowels, which were lost in all other Eskimo-Aleut languages (e.g., Proto-Eskimo **ataRuciR*, Sirenikski *ategesegh*, Central Alaskan Yup'ik *atauciq*, Iñupiaq *atausiq* 'one'). It has, however, undergone sound changes quite different from other Eskimo languages. For

example, in all nonstressed (essentially, noninitial) syllables (as in the example given above) the vowel changed to schwa. Unfortunately, it was first discovered and described at the end of the 19th century, when it was already highly moribund; the last speaker died in the year 2000.

Inuit

Inuit is generally described as a language with four distinct dialect groups, each of which have their own recognizable subdialects; these groups include Alaskan Iñupiaq, spoken from the Seward Peninsula and north; Western Canadian Inuit (Western Canadian Inuktitut), spoken over a vast area of Central Arctic Canada from MacKenzie Coast to Repulse Bay; Eastern Canadian Inuktitut, spoken in Baffin Island, Arctic Quebec, and Labrador; and Greenlandic Kalaallisut (Greenlandic Inuktitut), spoken in Greenland (there is also a sizable population of speakers in Denmark). Characteristic of Inuit are

- lack of intonational stress as compared with Yupik;
- loss of the fourth vowel, with various important phonological traces;
- various degrees of consonant and vowel cluster simplifications (cf. Iñupiaq *aglaun* 'pen,' Greenlandic *allaat* 'pen,' in which /gl/ became /ɬ/ and /au/ became /aa/);
- a tendency to merge parts of the mood system most important in narration, with most extensive merging in Alaska and least in Greenland.

All Inuit dialects have borrowed extensively from the respective languages of colonization. Most loans are from English in Alaska and Canada (although there are also French and German loans in eastern Canada, through the influence of missionaries) and from Danish in Greenland. The status and viability of the Inuit language is quite different in the different regions. In Alaska and western Canada, the language is severely endangered, with only about 3000 speakers, almost none of whom are children. In eastern Canada, there are about 20 000 speakers, but there is widespread bilingualism in almost all age groups and a growing tendency for English to replace Inuktitut. Active efforts are under way to reverse this process, including the encouragement of Inuktitut programs in schools. In Greenland, however, over 95% of the native population of some 50 000 are speakers of Kalaallisut, and the language is thriving.

Esperanto

J C Wells, University College, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Esperanto is a constructed language intended for international use. Originating as an artificial language, it is unique in that it has enjoyed sufficient success to have acquired a speech community and even to have undergone a degree of creolization. Consequently, the epithet 'artificial' is arguably no longer applicable. Unlike computer languages and codes, Esperanto generally satisfies the criteria for recognition as a form of natural language. However, its proponents' hopes of its being generally adopted for international use have not been realized, and its future must be seen as uncertain.

Background

The creator of Esperanto was Ludovic Lazar Zamenhof, a Jewish oculist of Warsaw, who used the pseudonym Doktoro Esperanto, 'the one who hopes'. His *Lingvo internacia* was first published in 1887, in Russian. By the beginning of the 20th century, Esperanto, as the language itself quickly came to be known, had been taken up in France, Germany, and elsewhere; the London Esperanto Club (still in existence) was founded in 1903. The participants at the first International Esperanto Congress, held in 1905 in Boulogne-sur-Mer, proclaimed the essential linguistic basis (*Fundamento*) of the language as inviolable. Support has subsequently spread to most parts of the world, including Japan, China, and Brazil (although the movement remains very weak in most of the Third World). Both Stalin and Hitler saw the internationalist and idealist values of Esperanto as a threat and launched persecutions of its supporters (Lins, 1988). As of 2004, the number of speakers of Esperanto is unknown, but variously estimated as between one or two hundred thousand and several million. Universala Esperanto-Asocio, with headquarters in Rotterdam, has members in over 100 countries. Esperanto speakers in the news recently include 1994 Nobel laureate in economics Reinhard Selten, 1996 World Chess Champion Zsuzsa Polgar, and Tivadar Soros, father of financier George Soros.

The annual World Esperanto Congress – held entirely in Esperanto – regularly attracts participants in the thousands. The attached sound files are of speakers addressing this assembly, in 1964 and 1995 respectively: Ivo Lapenna (1911–1987), professor of international law at the London School of Economics, whose mother tongue was Croatian, and the author of this article, John Wells (1939–), whose mother tongue is English.

It must be emphasized that Esperanto is a real language, both spoken and written, successfully used as a means of communication between people who have no other common language. For the great majority of its users, of course, it is a second language, learned well after the acquisition of the L1, so that levels of competence vary widely. However, for some speakers, children of parents who use Esperanto as a family language, it is a native language or mother tongue, normally in a bilingual or trilingual relationship with the language of the local community or other parental language(s). There is no other case in linguistic history of something that started as an intellectual scheme, a project on paper, being transformed into a language with native speakers of the second and, indeed, the third generation.

The traditional aim of the Esperanto movement is the adoption of Esperanto as L2 for all mankind. The chief arguments for this can be summarized by saying that Esperanto is easy to learn and politically neutral.

- *Ease of learning* is a consequence of the complete regularity of the language: grammatical rules have no exceptions, and the agglutinative morphological structure (discussed in the morphology section) makes vocabulary acquisition much faster than for other languages. As a result, it is claimed, Esperanto can be learned three to ten times as fast as national or ethnic languages (although obviously the rate of progress depends, as always, on many factors, including the learner's L1).

Esperanto is a constructed language intended for international use. Originating as an artificial language, it is unique in that it has enjoyed sufficient success to have acquired a speech community and even to have undergone a degree of creolization. Consequently, the epithet 'artificial' is arguably no longer applicable. Unlike computer languages and codes, Esperanto generally satisfies the criteria for recognition as a form of natural language. However, its proponents' hopes of its being generally adopted for international use have not been realized, and its future must be seen as uncertain.

Background

The creator of Esperanto was Ludovic Lazar Zamenhof, a Jewish oculist of Warsaw, who used the pseudonym Doktoro Esperanto, 'the one who hopes'. His *Lingvo internacia* was first published in 1887, in Russian. By the beginning of the 20th century, Esperanto, as the language itself quickly came to be known, had been taken up in France, Germany, and elsewhere; the London Esperanto Club (still in existence) was founded in 1903. The participants at the first International Esperanto Congress, held in 1905 in Boulogne-sur-Mer, proclaimed the essential linguistic basis (*Fundamento*) of the language as inviolable. Support has subsequently spread to most parts of the world, including Japan, China, and Brazil (although the movement remains very weak in most of the Third World). Both Stalin and Hitler saw the internationalist and idealist values of Esperanto as a threat and launched persecutions of its supporters (Lins, 1988). As of 2004, the number of speakers of Esperanto is unknown, but variously estimated as between one or two hundred thousand and several million. Universala Esperanto-Asocio, with headquarters in Rotterdam, has members in over 100 countries. Esperanto speakers in the news recently include 1994 Nobel laureate in economics Reinhard Selten, 1996 World Chess Champion Zsuzsa Polgar, and Tivadar Soros, father of financier George Soros.

The annual World Esperanto Congress – held entirely in Esperanto – regularly attracts participants in the thousands. The attached sound files are of speakers addressing this assembly, in 1964 and 1995 respectively: Ivo Lapenna (1911–1987), professor of international law at the London School of Economics, whose mother tongue was Croatian, and the author of this article, John Wells (1939–), whose mother tongue is English.

It must be emphasized that Esperanto is a real language, both spoken and written, successfully used as a means of communication between people who have no other common language. For the great majority of its users, of course, it is a second language, learned well after the acquisition of the L1, so that levels of competence vary widely. However, for some speakers, children of parents who use Esperanto as a family language, it is a native language or mother tongue, normally in a bilingual or trilingual relationship with the language of the local community or other parental language(s). There is no other case in linguistic history of something that started as an intellectual scheme, a project on paper, being transformed into a language with native speakers of the second and, indeed, the third generation.

The traditional aim of the Esperanto movement is the adoption of Esperanto as L2 for all mankind. The chief arguments for this can be summarized by saying that Esperanto is easy to learn and politically neutral.

- *Ease of learning* is a consequence of the complete regularity of the language: grammatical rules have no exceptions, and the agglutinative morphological structure (discussed in the morphology section) makes vocabulary acquisition much faster than for other languages. As a result, it is claimed, Esperanto can be learned three to ten times as fast as national or ethnic languages (although obviously the rate of progress depends, as always, on many factors, including the learner's L1).

- *Political neutrality:* Esperanto belongs to no particular nation or ethnic group. This, it is claimed, makes it politically a better choice for an international common language than English (seen by many as irredeemably attached to parochial U.K. or U.S. values) or other national languages.

Opposition to Esperanto is often more emotional than rational. Serious critics, however, argue that Esperanto is a language without culture (although supporters of Esperanto would dispute this, pointing to over a hundred years' literary activity, including a substantial body of original poetry), and second, that it is too European (though all alternative solutions to the question of an international language are even more so). In any case, it is claimed, the economic, social, and political pressures in favor of the choice of English for international use are by now overwhelming.

In light of the perceived success of English in filling the role for which Esperanto was intended, one group (not the majority) within the Esperanto movement has redefined its aims as securing linguistic rights as a 'stateless diaspora linguistic collective.' It sees the speakers of Esperanto as being comparable to the speakers of other endangered or minority languages.

Pronunciation and Orthography

The phoneme system comprises 23 consonants and 5 vowels. The consonants are plosives /p b t d k g/, fricatives /f v s z ʃ ʒ x h/, affricates /ts tʃ dʒ/, nasals /m n/, liquids /l r/ and glides /j w/ (the latter only after a vowel). The vowels are /i, e, a, o, u/. Word stress is always penultimate. Orthography is strictly phonemic, using the Latin alphabet and including the following letters bearing diacritics: *ĉ* /tʃ/, *ĝ* /dʒ/, *ĥ* /x/, *ĵ* /ʒ/, *ŝ* /ʃ/, and *ŭ* /w/.

An international standard of 'good' pronunciation has by now evolved and includes the avoidance of marked interference from speakers' L1s. Intonation follows general, mainly European, models without parochialisms.

Morphology and Syntax

Esperanto syntax and morphology show strong Slavic influences. Its morphemes are invariant and can be almost indefinitely recombined into different words. The internal word structure has affinity with agglutinative languages in that all words (other than function words) consist of a stem plus a grammatical ending (*-o* for nouns, *-a* for adjectives, *-i* for infinitive verbs, etc.: *telefon-o* 'a telephone', *telefon-a* 'telephonic,' *telefon-i* 'to telephone'). The plural ending is *-j* (*telephonoj* 'telephones'). There is an accusative case *-n*, used for the direct object. Adjectives agree with nouns in number and case: *mi vidis grandan hundon* 'I saw a big dog,' *du grandaj hundoj atakis min* 'two big dogs attacked me.' There are three verb tenses, *-as* present, *-is* past, and *-os* future, plus *-us* conditional and *-u* interative/volitive. The definite article, invariant, is *la*; there is no indefinite article. The grammar is entirely regular and without exceptions.

The normal word order is SVO. Determiners and adjectives usually precede nouns, and the language is prepositional. However, the morphological marking of the accusative means that the order of constituents is flexible and can be rather freely scrambled. The last sentence quoted has emphatic or stylistic variants such as *atakis min du hundoj grandaj*.

The stem of a word may be a single root (base morpheme) or a combination of roots and/or affixes: for example,

(1) *parol-ant-o*
speak-pres.ppl-NOUN
'speaker'

(2) *parol-em-a*
speak-tending-ADJ
'talkative'

(3) *mar-bord-o*
sea-edge-NOUN
'seaside'

Each morpheme (root, affix, ending) is in principle unvarying in form and meaning; the meaning of a compound of affixed form is the sum of the meanings of its constituent elements. A 20th-century development is the increasing use of affixes as independent stems, for example, *em-o* 'inclination.'

Vocabulary

The lexical material was chosen by Zamenhof to be as international as possible. Some three-fourths of the basic roots are of Romance origin, with the remainder mostly Germanic or Slavic; often they are common to several source families (e.g., *dom-* 'house'). Classical and international roots are readily incorporated, though adapted to Esperanto phonology and morphology; thus since *teatr-o* is 'theater,' 'theatrical' must be *teatr-a*. Given *telefon-o* 'telephone,' *telefone* is automatically the adverb 'by telephone' and *telefoni* the verb 'to telephone.' The extensive use of affixes means that the vocabulary is highly structured and comparatively easy to learn. From *vidi* 'to see,' dozens of derivatives such as *videbla* 'visible,' *videbligi* 'to render visible,' and *nevidebleco* 'invisibility' can be regularly and predictably formed.

General

The language is monitored by an Academy (Akademio de Esperanto). This does not, however, inhibit individual speakers from constant linguistic creativity. Many Esperanto speakers enjoy debating linguistic issues and arguing about vocabulary innovations. It is only recently that computing terminology has settled down, with *komputilo* (regularly formed by the suffix *-il-* 'instrument,' cf. *hakilo* 'ax') as the term for 'computer' and technical expressions such as *elŝuti* 'to download.' Popular spoken Esperanto occasionally deviates from the written norm. For example, although the official form of the word for 'tax' is *imposto*, and this is the only form given in dictionaries, in spoken Esperanto the form *impoŝto* can be heard from time to time (because of contamination from *poŝto* 'post, mail'). The standard and written word for 'plastic' is *plasta*, but in conversation *plastika* is also heard. The existence of such 'incorrect' spoken forms can be interpreted as an indication that the language is truly socially embedded ('living').

With a speech community scattered around the world, but nevertheless commanding great feelings of loyalty from its speakers, Esperanto is indeed comparable in some ways to diaspora languages such as Romani, Yiddish, or Armenian. In its lack of official government status, it is like creoles and many ethnic minority languages. It remains to be seen whether in the last analysis it is a linguistic curiosity doomed to disappear or a brilliant idea whose moment has not yet come.

Essential Indexical

K Romdenh-Romluc, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Indexicals are linguistic expressions such as 'I', 'here', and 'now' whose reference varies depending upon the context in which they are used (*see* **Indexicality: Theory**). Many writers, including Castañeda (1966, 1967, 1968), Perry (1979), and Chisholm (1981), have argued that indexicals are irreducible to other modes of reference, such as names and definite descriptions. 'I' in my statement 'I am hungry,' e.g., cannot be replaced with the co-referring expression 'Komarine' without loss of cognitive impact, since I may believe that Komarine is hungry without realizing that Komarine is me. The same applies to uses of 'here' and 'now.' It is also claimed that the thoughts

expressed using indexicals have a privileged role. The central insight is perhaps best appreciated if we consider Perry's claim that indexicals are essential for characterizing beliefs that motivate action (see also Castañeda, 1966, 1967, 1968). I may see myself in a mirror and notice that the person I see reflected has dirt on her face, but unless I believe that *I* have a dirty face I will not wipe it. I may believe that the meeting starts at noon but will not be moved to act unless I believe that the meeting starts *now*. I may believe that the treasure is buried outside the old church, but I will not start digging unless I believe that the treasure is buried *here*. To act requires me to have beliefs about my surrounding environment and how I am situated with respect to it. Indexical beliefs provide for this because their content is essentially perspectival. It is this egocentric dimension that is lost if the indexical is replaced with a non-indexical term, which is why indexical expressions cannot be reduced to other modes of reference.

Perry (1979) famously argued that indexicals pose a problem for the traditional Fregean account of belief. According to this theory, beliefs are relations between subjects and propositions. The belief report 'Komarine believes that Fido is a dog' states that an individual – Komarine – stands in the relation of believing to the proposition 'Fido is a dog.' The problem arises because the Fregean view implies (i) propositions are held to be true or false timelessly – not only true or false at a particular time, in a particular place, expressed by a particular person, and (ii) propositions are not individuated only by the ordinary objects that the proposition is about, but also by something like the conceptual components of the proposition that affect its cognitive impact. The propositions 'Hesperus is Venus' and 'Phosphorus is Venus' are about the same object, the planet Venus, but they are nevertheless different propositions since they are composed of different concepts. It is easy to see why indexicals pose a problem given the need to simultaneously satisfy (i) and (ii). A sentence such as 'I am hungry' does not pick out a proposition since its truth-value varies from context to context. To identify the proposition I believe when I utter 'I am hungry,' we need to specify some conceptual component associated with the term 'I.' To satisfy (i), the specification must yield a proposition that is timelessly true or false; to satisfy (ii), it must preserve the cognitive impact of 'I am hungry.' But as we saw above, there is no way of rendering 'I am hungry' as a proposition that is timelessly true or false without losing its cognitive impact. Various solutions to the problem have been proposed. Some attempt to refine the traditional account of belief (see, e.g., Evans, 1985), while others reject it in favor of a theory that can deal with the problem (see, e.g., Perry, 1986).

We sometimes attribute a use of an essential indexical to someone else. The usual way to do this is to use an *oratio obliqua* construction. I can, e.g., attribute the thought 'I am going to be late for work' to Sue by uttering, 'Sue thinks that she herself is going to be late for work.' Similarly, if Richard is in Malaga and thinks 'It is hot here,' I can attribute this thought to him by uttering 'Richard is in Malaga; he says it is hot there.' If Teresa thinks at 12 o'clock, 'It is now time to go to the meeting,' I can attribute this thought to her by uttering, 'Teresa thought at 12 o'clock that it was then time to go to the meeting.' (The alternative is to employ an *oratio recta* construction, e.g., 'Sue thinks: I am going to be late for work.') Castañeda (1966, 1967, 1968) labels expressions that attribute a use of an essential indexical to someone else in *oratio obliqua* constructions 'quasi-indicators.' Like essential indexicals, quasi-indicators cannot be replaced with co-referring expressions without loss of cognitive impact. 'Sue thinks that Sue is going to be late for work' and 'Sue thinks that she herself is going to be late for work' attribute different thoughts to Sue, since she may have amnesia and forget that she is called 'Sue.' Thus, quasi-indicators raise the same kind of issues as essential indexicals. There are further problems associated with their use. Essential indexicals create difficulties for the traditional Fregean account of belief because the beliefs they express are essentially tied to the perspective of the believer. It is puzzling, therefore, how a listener can grasp the content of another's indexical utterances, and further, convey that content to someone else. Again, there is disagreement concerning how the content of quasi-indexical attitudes – those expressed using quasi-indicators – should be understood.

Estonia: Language Situation

A Verschik, Tallinn, Estonia

© 2006 Elsevier Ltd. All rights reserved.

According to the census of 2000, 142 different ethnicities live in Estonia. The total population amounts to 1 370 053. The largest ethnic groups are Estonians (67.9%, or 930 219) and Russians (25.6%, or 351 178). As a result of the Soviet (1940–1941, 1944–1991) and Nazi occupations (1941–1944), the demographic situation changed drastically, due to emigration (Baltic Germans), plight (Swedes, Estonians), deportations (mainly Estonians), or virtual extinction of indigenous minorities (Jews, Roma). In addition, the number of ethnic Estonians decreased (from 88.2% in 1934 to 61.5% in 1989) on account of the increasing number of Russians and Russian speakers. The latter were encouraged by Moscow to settle in Estonia and other non-Russian countries incorporated into the USSR. Due to higher living standards and a more European-like culture, the three Baltic republics (Estonia, Latvia, and Lithuania) had acquired a reputation of 'the Soviet West.' Russian speakers from the USSR settled in urban and industrial areas and now constitute a majority in northeastern Estonia.

The attempts of overt and covert Russification failed, due largely to the high prestige of Estonian among its speakers. Despite Russification efforts, the network of schools and universities functioning in Estonian was maintained throughout the Soviet occupation. Ethnic Russians and ethnic Estonians formed two separate communities with little or no interaction. Estonians working in the public sphere had a working command of Russian, but very few Russians learned any Estonian.

The so-called third ethnicities (neither Russians nor Estonians) had to choose between schools with Russian and with Estonian as the language of instruction for their children. As opposed to the remaining members of indigenous minorities with the roots in pre-1940 Estonia, the non-Russian newcomers had little knowledge of and little interest in the Estonian culture and language and, usually, had already acquired a certain command of Russian. The choice of Russian-language education for their children appeared logical, but on the other hand, it contributed to the further Russification of these ethnicities.

Since 1989, Estonian has been the official language. After the regaining of independence in 1991, Estonian became a compulsory subject in schools with a non-Estonian language of instruction, and jobs in the public sector require proficiency in Estonian. The knowledge of the language among non-Estonians has increased. In the last Soviet census (1989), 15% of Russians claimed to know Estonian, whereas by 2000 this figure had reached 44%. Nevertheless, language loyalty is high in the two largest ethnic groups. By the law, at least two foreign languages must be taught in every school. Primary education in one's mother tongue is guaranteed by the state; in addition, there exist Estonian immersion schools and Russian-Estonian bilingual schools. The knowledge of English is becoming common. In the capital, Tallinn, many people understand and can speak Finnish. The cultural life and activities of the minorities are being promoted in the spirit of the prewar tradition of cultural autonomy. In 2004 the Estonian Bureau for the Lesser Used Languages (EstBLUL) was established, representing speakers of Tatar, Russian, Yiddish, Romani, German (Standard German), Finnish, and Võru-Setu (a newly created regional standard based on Võru and Setu dialects of Southern Estonia).

Estonian, a Baltic–Finnic language within the Uralic family, is represented by over a million speakers, as the official language of Estonia as well as actively maintained by émigrés in Sweden, Canada, and elsewhere. The diverse Estonian dialects may be divided into a northern group and a southern group, with Tallinn and Tartu as their respective cultural centers. Standard Estonian, in large part based on the northern dialects, underwent significant adjustment at the hands of language planners during the twentieth century to provide a compromise literary medium suitable for all areas. In contrast with nationalist movements in other countries, foreign loanwords have been tolerated, in part motivated by a desire to facilitate access to Western European culture. The resulting standardization, however, has commonly forced Estonians to consult an extensive orthographic manual for spelling and morphological norms.

The history of Estonian must be projected from reconstruction, as apart from fragments dating from ca. 1220, the first written texts appeared in the sixteenth century, beginning with the Kullamaa prayers in the 1520s. In its development the interaction of inherited features with those of contact languages (including governing superstrata, especially German) has played a major role in shaping its unique structure.

Estonian phonology is characterized by an abundance of vowels (/i ü u e ö o ä a/ plus a midcentral unrounded /õ/), few consonants (/p t k s h m n l r y v/ plus palatalized /t^y s^y n^y l^y/—and /f š/ in loans), and a richness of stressed syllable structures resulting from contrastive vowel length (*a* versus long *aa*) tautosyllabic vowel clusters (e.g., *ea*, *eo*, *õa*), and geminate consonants (*ala* versus *alla*). The writing system is based on the Latin alphabet, augmented by diacritics (*ü*, *õ*), but palatalization is not represented. Initial stress is the rule, but loans often preserve noninitial stress (*hotell*), and multiple word stresses may result from morphology (*tulemata*) < /tule + ma + tta/—with a second stress, often stronger, on the third syllable).

Typologically the most salient feature of Estonian is its extrasegmental quantitative prosody, by which stressed heavy syllables contrast in two types of quantity and tonal contour; for example, segmental /saata/ *saada* together with prosodic quantity may yield [sa:ta] 'send!' (long *a*) or [sa::ta] 'to become' (overlong *a*); *linna*, [linna] 'city (gen.)' or [lin:na] 'into city'; *osta*, [osta] 'buy!' or [os:ta] 'to buy' (contrast here /sata/ *sada* 'hundred,' *lina* 'linen,' with light first syllables). The first syllable of a form such as /saatta/ *saata* 'to send' may occur with the overlong prosodic quantity without requiring individual component segments (/aa/ or /tt/) to be overlong. Prosodic quantity is noted in spelling only for intervocalic *p*, *t*, *k*; e.g., [ata] as *ada*, [atta] as *ata*, and [at:ta] as *atta*.

The palatalized coronal consonants /t^y s^y n^y l^y/ are of special interest, since these reflect an earlier Umlaut-like process (contrasting typologically with their Slavic counterparts in the absence of a prominent offset transition). This palatalization produces a *y*-like onset transition from a preceding stressed vowel (triggered by an [earlier] *i* in the following syllable); e.g., /kas^{y}k/ *kask* = [ka^{y}sk] <*kaski 'birch' (contrast the absence of palatalization in *kaks* < *kaksi 'two').

Estonian Lexicography

M Langemets, Institute of the Estonian Language, Tallinn, Estonia

© 2006 Elsevier Ltd. All rights reserved.

Antecedents: German-Influenced Bilingual Dictionaries

The history of Estonian lexicography dates back to the early 17th century, when Germans hardly fluent in Estonian wrote Estonian grammars for German-speaking Lutheran pastors, adding small bilingual German–Estonian glossaries as supplements. German remained the focus of almost all lexicographic work done in Estonia for about two centuries.

Estonian first became the source language of bilingual German dictionaries in the 18th century Vestring (1720?), its printed version (Helle, 1732), and Hupel (1780) are accepted as the best lexicographic sources of that period.

The late 19th century brought a change: the previous North- and South-Estonian standards both provided for a unified national standard, while Estonian excited a growing linguistic interest. The lexicographic masterpiece of the period is the scholarly *Ehstnisch-deutsches Wörterbuch* by F. J. Wiedemann (1869) providing abundant linguistic information on 50 000 Estonian words and covering all regional variations (largely due to the author's extensive fieldwork).

1900–1980s: From the First Monolingual Dictionaries to the Computer Era

In the early decades of the 20th century the development of standard Estonian was accelerated. The principles of language planning were worked out, and the language was modernized and standardized. In the Republic of Estonia, born in 1918, the literary standard was based on the first normative orthological dictionary of Estonian (ORTH, 1918), introducing a long tradition of dictionaries of this special type (without definitions). The first (ORTH, 1918) was followed by Veski and Muuk (1925–1937), Muuk (1933), Nurm, Raiet, and Kindlam (1960), Raiet and Kull (1976), and Erelt (1999) with many reprints. The language of science was shaped by numerous terminological dictionaries, while several excellent bilingual dictionaries were also published, particularly for English (Silvet, 1939–1940) and Finnish (Mägiste, 1931).

The years of Soviet occupation (1940–1991) disrupted the previous linguistic life and split Estonian lexicography in two. In exile, two voluminous dictionaries were published: the thesaurus by Saareste (1958–1963) and the Estonian–English dictionary by Saagpakk (1955). Dictionaries published in Estonia in the 1960s reveal a strong Russian impact, both linguistic and ideological; later, this pressure was alleviated. Nevertheless, language remained one of the most powerful tokens of Estonian identity. In the 1960s, compilation of the first comprehensive dictionary of Estonian (EKSS) was started – roughly 200–300 years later than those of French, English, or German and 100 years later than in the Nordic countries – while the first fascicle appeared in 1988. The first fascicle of the dictionary of Estonian dialects (EMS) was published in 1994, also originating from the1960s.

The history of computational lexicography begins in the late 1970s when the revised electronic version (1980) of the orthological dictionary (Raiet and Kull, 1976) was completed. From this time onward, all dictionaries – including the first comprehensive monolingual Estonian dictionary (EKSS) – have been digitized, using a descriptive and, later, SGML markup.

Current Developments

In 1989 the Law on Language declared Estonian the sole state language of Estonia. The restoration of Estonian independence in 1991 has conditioned massive changes in Estonian society, including linguistic life (expansion of researcher contacts), as well as in the language (influx of new borrowings). Today there are two main lexicological centres in Estonia – Institute of the Estonian Language (Tallinn) and the University of Tartu. Long-term scholarly dictionaries are financed by national programs.

Language technology (corpora, electronic dictionaries, automatic morphology, software localization, etc.) is particularly advanced. Several printed dictionaries, both monolingual and bilingual, also exist in machine-readable form; a lexico-grammatical database of Estonian is in progress. Several dictionaries are available via the Internet or on CD. Corpora are acquiring an increasing role in Estonian linguistics, including lexicography. The Corpus of Standard Estonian (CSE), modeled on the classical Brown corpus, currently (2005) contains about 6 million words; the eventual aim is 100 million words. The Corpus of Early Written Estonian (CEWE) exists, as well as the Corpus of Estonian Speech (CES). The compilation of the Estonian WordNet (EstWN) – as part of the EuroWordNet – is also in progress.

Estonian dictionaries have a long tradition of presenting morphological information, as Estonian is characterized by a great number of inflected forms and extensive variation of morphological units. A special morphological dictionary (Viks, 1992) has contributed to three systems of automatic morphology. The morphology modules have been successfully used in lexicography for generating the grammar component in dictionary entries.

The most recent orthological dictionary (Erelt, 1999) represents a more lenient trend in language cultivation, providing recommendations rather than strict norms.

The comprehensive dictionary of Estonian (EKSS) is to be completed in 2007, thus taking nearly 50 years to produce – a time period common to many other countries. Work continues on the big dialect dictionary (EMS). Although lexicographers still face the challenge of filling in some gaps in Estonian lexicography, they are now in a good position to take advantage of new ideas.

Ethiopia as a Linguistic Area

J Crass, Universität Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The Ethiopian linguistic area is probably the most famous linguistic area in Africa. It is often the only African linguistic area discussed to any extent in general works dealing with language contact and areal linguistics (Masica, 1976; Thomason and Kaufman, 1988; Thomason, 2001). Most scholars refer to this area as the Ethiopian language area (Ferguson, 1976; Sasse, 1986; Hayward, 1991; Zaborski, 1991, 2003; Tosco, 1994; Crass, 2002). This term, however, is problematic in several respects. First, the English translation of the German term *Sprachbund* is linguistic area, convergence area, or diffusion area (Campbell, 1994: 1471). Second, the area includes Eritrea, which was a province of Ethiopia until it became an independent state in 1993. Third, a certain number of features are found beyond Ethiopia and Eritrea in languages spoken in neighboring countries, such as Djibouti, Somalia, and Sudan, and even beyond. Some scholars have taken these facts into account, at least to some extent. Hayward (2000: 623) uses the term Ethio-Eritrean Sprachbund; Zaborski (2003: 62) proposes North East African Language Macro-Area. Bender (2003a: 4) argues that the terms Northeast Africa area, Horn of Africa Language Area, and Erythraean Area "all have their plusses and minuses" and stresses that "now we must modify it to Ethiopia-Eritrean Area." In the present article, the term Ethiopian linguistic area (ELA) is used in order because (1) language area is not the correct term in areal linguistics and (2) the core of the area is Ethiopia.

Most of the approximately 80 languages spoken in Ethiopia and Eritrea belong to three language families of the Afroasiatic phylum: Semitic, Cushitic, and Omotic. A number of languages in the west and in the southwest belong to various families of the Nilo-Saharan phylum.

According to a widely accepted view, Semitic-speaking peoples arrived in the Horn of Africa at the end of the first millennium B.C. by crossing the Red Sea after having left their home on the Arabian Peninsula. They migrated into the area of today's Ethiopia and Eritrea and underwent extensive linguistic and extra-linguistic influence due to contact with Cushitic-speaking peoples (Ullendorff, 1955). A contradictory view considers Ethiopia and Eritrea to be the original homeland of Semitic-speaking people (Murtonen, 1967; Hudson, 1977). This view is based on the observation that the linguistic diversity among Semitic languages in Ethiopia and Eritrea is much greater than elsewhere.

The proposed features defining the ELA differ considerably from author to author, and the validity of these features has been discussed by the authors previously mentioned.. Recently, even the existence of an ELA was rejected by Tosco (2000).

Research History

Leslau (1945) and Moreno (1948) are two early attempts to describe the influence of Cushitic languages on Ethiopian Semitic languages. The first to claim the existence of a linguistic area in "Ethiopia and the various Somalilands" was Greenberg (1959: 24). He argues that this area is marked by "relatively complex consonantal systems, including glottalized sounds, absence of tone, word order of determined followed by determiner [*sic*], closed syllables, and some characteristic idioms." According to Heine (1975: 41ff.), who deals with word order, Ethiopia is part of "probably the largest convergence area in Africa, stretching in a broad belt from the Lake Chad region in the west to the Red Sea and the Indian Ocean in the east."

Ferguson (1970, 1976) was the first to describe the ELA in more detail. The second of these articles, with an extended database and improvements and corrections, is still the reference work for all scholars. Therefore, Ferguson (1976) is the starting point when in the following discussion of phonological and grammatical features. Ferguson discusses eight phonological and eighteen grammatical areal features for 18 languages, including Arabic and English. He is of the opinion that the "languages of Ethiopia constitute a linguistic area in the sense that they tend to share a number of features which, taken together, distinguish them from any other geographically defined group of languages in the world" (Ferguson, 1976: 63f.). He stresses that "some of these shared features are due to genetic relationship [...], while others result from the process of reciprocal diffusion among languages which have been in contact for many centuries" (Ferguson, 1976: 64).

Zaborski (1991: 124) criticizes Ferguson's selection of languages and features. He is of the opinion that the languages were "rather random[ly] selected" and that "most of the alleged areal features are not really areal but of common genetic origin." Hayward (2000: 623) argues that a number of Ferguson's features are "characteristic of most languages of this region"; five of these features he considers to

be "very widespread." Some articles deal with only one areal feature: Appleyard (1989) discusses relative verbs in focus constructions, Tosco (1994) deals with case marking, and Tosco (1996) deals with extended verb paradigms in the Gurage-Sidamo subarea.

Tosco (2000) is a controversial paper. In it, he denies the existence of an ELA because of the genetic relatedness of Ethiopian Semitic and Cushitic languages, the unilateral diffusion from Cushitic to Ethiopian Semitic, and the occurrence of features in related languages that do not belong to the ELA. Four recent papers, Bender (2003b), Crass (2002), Crass and Bisang (2004), and Zaborski (2003: 62f), favor the existence of a linguistic area. Bender (2003b) argues against the conclusions in Tosco (2000) and tries to extend the ELA by testing a number of Nilo-Saharan languages using a selection of Ferguson's features. Crass (2002) discusses two phonological features in detail; in Crass and Bisang (2004), the discussion is extended to features such as word order, converbs, and ideophones verbalized by the verb 'to say'. Zaborski (2003) presents the most extensive list, including 28 features that he considers to be valid for a macroarea that includes Ethiopia, Eritrea, Djibouti, Somalia, and parts of Sudan, Kenya, and even Tanzania and Uganda. Finally, Hayward (1991) deals with patterns of lexicalization shared by the three Ethiopian languages, Amharic (Semitic), West-Central Oromo (Cushitic), and Gamo (Gamo-Gofa-Dawro; Omotic). According to Hayward (1991: 140), these lexicalizations reinforce "the very real cultural unity of Ethiopia." This topic is reopened in Hayward (2000).

The ELA is considered to be composed of several subareas. Leslau (1952, 1959) describes change in Ethiopian Semitic languages induced by contact with neighboring Highland East Cushitic languages. Sasse (1986) deals with the Sagan area in southwest Ethiopia, and Zaborski (1991: 125) gives a list of seven subareas that are composed of "smaller contact and interference units," which he extends to nine by adding a Kenyan and an Tanzanian subarea (Zaborski 2003: 64).

Phonological Features

The eight phonological features listed by Ferguson (1976: 65ff.) are

P1: /f/ replacing /p/ as the counterpart of /b/
P2: palatalization of dental consonants as a common grammatical process in at least one major word class
P3: the occurrence of ejectives (in Ferguson's terminology, glottalic consonants)
P4: the occurrence of an implosive /ɗ/
P5: the occurrence of pharyngeal fricatives
P6: the occurrence of consonant germination
P7: the occurrence of central vowels
P8: the occurrence of an epenthetic vowel

Ferguson's list has since been criticized by several scholars. Zaborski (1991: 114 fn. 3) considers only P3 and "with reservations" P2 to be "really areal." In his more recent paper, Zaborski (2003: 62) lists only four phonological features for ELA. In addition to P3 and P6, he argues that "labialized consonants are frequent [and that] some palatalized consonants are innovations." Tosco (2000: 341), in contrast, is of the opinion that P1, P2, P3, and P5 are genetically inherited within the Afroasiatic phylum; that P4, P7, and P8 are restricted to one or two language families; and that P6 is widespread in both the Afroasiatic and the Nilo-Saharan phyla. But according to Bender (2003a: 3, 2003b: 32), P2 and P6 are typological features, P5 is too limited, and P8 "is vacuous because consonant clusters are rare" (Bender, 2003a: 3). P1, P3, P4, and P7, however, are "fairly idiosyncratic and easy to check" (Bender, 2003b: 32). Hayward (2000: 623) explicitly mentions only P6, which he considers to be areal. Crass (2002) discusses the ejectives and pharyngeal fricatives (P3 and P5) in detail. Because both features are genetically inherited within the Afroasiatic phylum, Crass argues that their occurrence (in the case of ejectives) and nonoccurrence (in the case of pharyngeal fricatives) can be considered areal features. Reconstructions of different stages of proto-languages of Afroasiatic show that ejectives were lost over the course of time (for details, see Crass, 2002: 1683); in recent times, however, ejectives were reimported into most of the languages via contact. In Proto-Highland East Cushitic, for example, only one ejective is attested, the velar ejective. In most of the modern Highland East Cushitic languages, however, four ejectives occur as phonemes: the dental, the postalveolar affricate, the velar, and to a lesser extent the labial ejective (Hudson, 1989: 11). In the Agaw languages (Central Cushitic), ejectives occur predominantly in loan words from Amharic and Tigrinya (Tigrigna) and their phonemic status is problematic (cf. Appleyard, 1984: 34).

The reasons for the nonoccurrence of pharyngeal fricatives in most of the languages of central Ethiopia are unclear. The nonoccurrence may be due to language contact or due to language-internal change. Tosco (2000: 343) supports Crass's idea in arguing that the nonoccurrence of pharyngeal fricatives "could identify a smaller 'central Ethiopian area' . . .

in which pharyngeal consonants are either dropped or reduced."

Grammatical Features

Ferguson's (1976: 69ff.) grammatical features are

G1: SOV word order
G2: subordinate clauses precede main clauses
G3: converb
G4: postpositions
G5: quotation marked by the verb 'to say' (in Ferguson's terminology, quoting clauses)
G6: "compound verbs ... consisting of a noun-like or interjection-like 'preverb' plus a semantically colourless auxiliary, commonly the verb 'to say'" (Ferguson, 1976: 71f.)
G7: negative copula
G8: singular used with numbers
G9: possessive suffixes identical or nearly identical with object suffixes added to the verb
G10: masculine/feminine gender distinction in the second- and third-person singular of pronouns and verbs
G11: identical subject prefixes for the second-person masculine singular and the third-person feminine singular marking a certain tense that contrast with subject suffixes forming other tenses
G12: for many words, a consonantal skeleton carrying the lexical meaning and a pattern of vowels carrying the grammatical meaning
G13: reduplication for forming intensive verbs and plurals of adjectives
G14: plural formation by change of the pattern (e.g., ablaut, called broken plurals)
G15: an independent and a subordinate form of the imperfective
G16: plural nouns agree with a feminine singular adjective, verb, or pronoun
G17: the imperative of the verb 'to come' is formed either from "a totally different stem [...] or with an exceptional formation" (Ferguson, 1976: 74)
G18: the unmarked form of a noun is not singular in number but plural or collective (Ferguson, 1976: 74)

Zaborski (1991: 124) considers G1 to G6 to be areal features and G7 to G18 to be due to genetic origin. Furthermore, he adds two features that he considers areal: (1) adjectives precede substantives and (2) main verbs precede auxiliaries. Hayward (2000: 623) is of the opinion that G1, G3, G6, and G15 are "very widespread." According to Bender (2003a: 3, 2003b: 32), G2, G3, G4, and G9 "are implicational consequences of SOV order," G13 and G18 are "too typological," and G10 to G12, G14, and G16 are Afroasiatic, "especially Semitic idiosyncrasies." In addition, G7 "looks like a good choice but turns out [...] to be inadequately defined." Bender seems to consider the features G1, G5, G6, G8, G15, and G17 to be good candidates for areal features.

Hayward (1991) and Tosco (2000) correctly stress that G2 and G4 have a relation to G1 and therefore cannot count as individual features. Within this context, Campbell (1994: 1471) raises the question of the weight of "a trait so central to the grammar" when it is counted only as a single feature. Also, G3, contrary to Bender's opinion, is not related to G1 (cf. Bisang, 2001) and is found in an area exceeding the ELA. Tosco (2000) considers G3 to have spread into Semitic languages due to Cushitic influence. According to Tosco, this holds true also for G5, G6, G8, G13, and G15. The features G11, G12, and G14 are strongly "Semitic-biased," and G17 and G18 are Afroasiatic features.

The huge list of areal features presented by Zaborski (2003: 62f.) contains features of differing quality. Unfortunately, in most cases Zaborski simply names the features without any discussion. A number of features relate to the basic SOV word order; examples are (1) dependent clauses precede main clauses, (2) main verbs precede auxiliary ones, (3) adjectives precede nouns that they define and (4) possessor (genitive) precedes the possessed. Other features are trivial or represent frequent grammaticalizations, such as (1) relative clauses are frequent, (2) cleft sentences are frequent, (3) subject is in the oblique case, and (4) postpositions start functioning as new case endings. However, there are a few interesting features that need further study, such as (1) quoting clauses and a lack (or at least limited use) of indirect speech and (2) a considerable number of different 'to be' auxiliary verbs.

Lexical Features

Hayward (1991) distinguishes three categories of lexicalizations, which he exemplifies with data from Amharic, Oromo, and Gamo. These categories are (1) single-sense lexicalizations, (2) lexicalizations with two or more distinct senses, and (3) lexicalizations involving similar derivations. The first category comprises "single-sense lexicalizations of typically indigenous concepts" (Hayward 1991: 145), the second category lexicalizations "showing inter-linguistic matching across the three languages" (Hayward 1991: 148), and the third category lexicalizations with a "similar (parallel) 'derivational pathway'" (Hayward 1991: 150). To the first category belong mainly nouns, such as lexical items for seasons of

the year, categories of terrain, categories of dung/excrement, supercategories for birds, types of borrowing, and the skin-color classification of people of the region. Furthermore, this category includes the suppletive imperative of the verb 'to come' (Ferguson's feature G17) and particles with the meaning 'take this!', which have no obvious etymological relationship to a verb. The second category, lexicalizations with two or more distinct senses, predominantly comprises verbs and some nouns; examples are the verb that has the basic meaning 'hold, catch' and the secondary meaning 'start, begin' and the verb that has the basic meaning 'play' and the secondary meaning 'chat'. The third category includes verbal derivations, compound verbs (Ferguson's feature G6), possessive constructions including two NPs, and idiomatic expressions. Examples of verbal derivations are the causative of the verb 'want', which has the meaning 'need'; the causative of the verb 'enter', which has the meaning 'marry'; and the causative of the verb 'pass the night', which has the meaning 'administer'. Examples of compound verbs are 'become silent', 'hurry up', and 'jump up suddenly'. Possessive constructions that include two NPs have a word-by-word meaning and a metaphorical meaning. Examples are 'son of man/people', with the metaphorical meaning 'mankind, human being', and 'land of man/people', with the metaphorical meaning 'foreign country'. Examples of idiomatic expressions are 'regain/recover control, take courage', which is composed of the noun 'heart' and the verb 'return (INTRANS)', and 'catch cold', in which the noun 'cold' is the subject and the experiencer is the object of the verb 'catch'.

Summary

The ELA is characterized by phonological, grammatical, and lexical features. Their areal status is not accepted by all scholars; furthermore, the existence of the ELA itself is not generally accepted. Most of the features are found in languages spoken in the highlands of Ethiopia. The more distant a given language is from this core area, the fewer features it has. However, because only a relatively small number of languages have been adequately described, these findings must be considered preliminary.

Ethiopia: Language Situation

M Yigezu, Addis Ababa University, Addis Ababa, Ethiopia

© 2006 Elsevier Ltd. All rights reserved.

Like many African countries, Ethiopia, which covers an area of 1 000 000 km^2, is linguistically and ethnically a very heterogeneous country. There are over 80 languages and approximately the same number of ethnic groups within a population officially reckoned to be about 54–63 million people, although unofficial estimates are between 68 and 70 million. Of the 80 or so languages, three major languages, Amharic, Oromo, and Tigrigna, comprise 70% of the total population (CSA, 1998). The language question is of paramount significance in the sociopolitical life of Ethiopians. The present government and its political ideology, for example, is based on 'ethnic federalism.' The constitution of 1995 also confers rights, including regional autonomy, to population groups on the basis of their ethnolinguistic character. Ethiopia's present geopolitical structure is thus primarily defined by language and ethnicity.

Language Families

The majority of the languages of Ethiopia belong to the Afro-Asiatic phylum and are classified under Semitic, Cushitic, and Omotic families. Others belong to the Koman and Chari-Nile subfamilies of the Nilo-Saharan phylum. The majority of the modern Semitic languages, most of the Cushitic, and all of the Omotic languages are strongly represented in Ethiopia. Over a dozen Nilo-Saharan languages are spoken at the periphery of the country bordering Sudan and Kenya. These are the least studied languages of Ethiopia.

There has always been uncertainty about the internal genetic classification of Ethiopian language groups (Bender *et al.*, 1976). There are also some unclassified languages: Ongota (Birale) and Shabo, spoken by very small communities in the southwestern corners of the country. Ethiopia has been considered as a 'language area' from a typological perspective and this was first suggested by Ferguson (1976). However, this view has been controversial among linguists and was opposed, for example, by Tosco (2003).

Like many African countries, Ethiopia, which covers an area of 1 000 000 km^2, is linguistically and ethnically a very heterogeneous country. There are over 80 languages and approximately the same number of ethnic groups within a population officially reckoned to be about 54–63 million people, although unofficial estimates are between 68 and 70 million. Of the 80 or so languages, three major languages, Amharic, Oromo, and Tigrigna, comprise 70% of the total population (CSA, 1998). The language question is of paramount significance in the sociopolitical life of Ethiopians. The present government and its political ideology, for example, is based on 'ethnic federalism.' The constitution of 1995 also confers rights, including regional autonomy, to population groups on the basis of their ethnolinguistic character. Ethiopia's present geopolitical structure is thus primarily defined by language and ethnicity.

Language Families

The majority of the languages of Ethiopia belong to the Afro-Asiatic phylum and are classified under Semitic, Cushitic, and Omotic families. Others belong to the Koman and Chari-Nile subfamilies of the Nilo-Saharan phylum. The majority of the modern Semitic languages, most of the Cushitic, and all of the Omotic languages are strongly represented in Ethiopia. Over a dozen Nilo-Saharan languages are spoken at the periphery of the country bordering Sudan and Kenya. These are the least studied languages of Ethiopia.

There has always been uncertainty about the internal genetic classification of Ethiopian language groups (Bender *et al.*, 1976). There are also some unclassified languages: Ongota (Birale) and Shabo, spoken by very small communities in the southwestern corners of the country. Ethiopia has been considered as a 'language area' from a typological perspective and this was first suggested by Ferguson (1976). However, this view has been controversial among linguists and was opposed, for example, by Tosco (2003).

Table 1 Endangered and/or extinct languages of Ethiopia

Languages	*Language family*	*Approximate number of speakers**
Ongota (Birale)	Unclassified	<10
Shabo	Unclassified	<200
Koegu (Kwegu)	Surmic, Nilo-Saharan	450
Opo (Opuuo)	Koman, Nilo-Saharan	<280
North Mao	Koman, Nilo-Saharan	<500
Argobba	Semitic, Afro-Asiatic	<1000
Zay	Semitic, Afro-Asiatic	<6000
Haro	Omotic, Afro-Asiatic	200
Kara (Karo)	Omotic, Afro-Asiatic	1000
Kimant	Cushitic, Afro-Asiatic	300
Anfillo	Omotic, Afro-Asiatic	Nearly extinct
Omo Murle (Murle)	Surmic, Nilo-Saharan	Extinct
Gafat	Semitic, Afro-Asiatic	Extinct
Geez	Semitic, Afro-Asiatic	Extinct

*The figures are estimates of the author based on personal experience and may not agree with official figures given in the past.

Language Policy and Education

Since 1991 Ethiopia has undergone dramatic socio-political changes, particularly in the education sector. One of these changes is the extension of the role of a number of languages for the purpose of primary education, which reflects a fundamental shift from bilingual to multilingual approaches to education. There are now about 21 vernaculars introduced into the Ethiopian school system as media of instruction and/or as subjects to be taught in primary schools, as well as being used for regional governmental and administrative activities.

Orthographies and Scripts

There are three scripts in use throughout the country: Ethiopic (Geez), Latin based and Arabic. Ethiopic is largely used for the Semitic languages such as Amharic, Tigrigna, Harari, and Gurage while many Cushitic and Omotic languages such as Oromo, Somali, Afar, Wolaytta, etc. have adopted the Latin alphabet. In areas where Arabic has a role as a language of literacy and religious study, the Arabic script is in use. Ethiopia is thus both a multilingual and a multiscriptual nation.

Multilingualism and Patterns of Language Use

Because of the changes noted above, the pattern of language use in Ethiopia has been influenced in a significant way. One of these changes concerns the status of Amharic. It was the official and national language of the country during the two previous governments, Haile Selassie's imperial government (1941–1974) and the Socialist Derg (1974–1991). Its status has now been reduced to (a) a school subject from grade 3 to grade 10, in regions where it is not used as a medium of instruction, (b) the working language of the federal government, and (c) the working language of some regions where two or more competing languages exist, such as Benishangul Gumuz and Gambella. In higher institutions Amharic continues to enjoy its status as a field of study at diploma, B.A. and M.A. levels. Recently, some major languages such as Oromo and Tigrigna have also been introduced in various colleges and universities as minor and major subjects of study for first degrees.

Languages with Special Status

There are also some languages with special status: Geez, Arabic, and English. Geez is an extinct language but has been in use as a liturgical language in the Ethiopian Orthodox Church for centuries. Classical Arabic has also been in use as a language of literacy and religious study since the 13th century. Ethiopia therefore possesses a wealth of manuscripts in Geez and classical Arabic that focuses on both religious and secular themes. English is the language of secondary and tertiary education and plays a role in modernization, business, and technology.

Language Maintenance and Shift

Ethiopia is one of the countries designated as being within a 'crisis area' in a report posted on the UNESCO website (2002), because it has the most moribund and seriously endangered languages in Africa. These include: Ongota (Birale), Shabo, Koegu (Kwegu), Opo (Opuuo), North Mao, Argobba, Zay, Haro, Kara (Karo), Kimant, Anfillo, Omo Murle (Murle), Gafat, and Geez (see Table 1).

Although Amharic is used as a *lingua franca*, it does not mean that the speakers of these endangered languages are shifting towards Amharic. Only speakers of some languages, for example, Geez (partly), Gafat, Argobba (partly), and Kimant, have shifted or are shifting toward Amharic. In some cases, the language shift is taking place towards other major languages such as Oromo (e.g., Anfillo). The language shift patterns vary and depend on various socioeconomic and demographic factors.

Ethiopian Semitic Languages

A Wetter, Johannes Gutenberg University, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

The Ethiopian Semitic (ES) languages form a subdivision of the Semitic language family that is a branch of the Afroasiatic superfamily. This subfamily comprises about 23 languages. Two languages (Tigre and Dahlik) are spoken only in Eritrea. Tigrinya (Tigrigna) is spoken in Eritrea and Ethiopia and all the others are in Ethiopia. (Unless otherwise specified, figures of speakers cited in this article are taken from the Ethnologue website.)

Classification and Demography

The still widely accepted classification of ES is based on shared "innovations due to internal reasons" (Hetzron, 1972: 13) and has two main divisions, a northern (NES) and a southern branch (SES). The northern group is formed by only four languages: the ancient Ge'ez (now extinct), Tigrinya (1 900 000 in Eritrea and 3 225 000 in Ethiopia), Tigre (800 000), and the recently identified Dahlik (1000) by Simeon-Senelle (2000). The southern branch, in contrast, comprises most of the languages and has a more complex composition, with several subgroups. This branch, according to Hetzron (1972), is classified into Transversal and Outer South ES. The languages forming the Transversal South ES are spoken in the central and center-eastern parts of Ethiopia and is subdivided into Central Transversal, consisting of Amharic (spoken as a first and second language by 80% of the 70 million total population of Ethiopia; cf. Meyer and Richter, 2003) and Argobba (10 000), and Eastern Transversal, consisting of the Eastern Gurage languages, i.e., Silt'e, Zay, and Wolane (together 900 000) and Harari (22 000), spoken in the city of Harar. The second subgroup, Outer South ES, contains all other languages that are divided into a 'n-group,' which consists of Gafat, a non-Gurage language that is extinct, and the North Gurage languages that comprise Goggot, Soddo (Gurage, Soddo), and, according to Leslau (1969) and Demeke (2001), Mäsqan, (together around 300 000) and a 'tt-group,' which comprises about nine different languages (Muher, Ezha, Chaha, Gumär, Gura, Gyeto, Ennemor, Endegen, and Endär, together 800 000). These languages are spoken in a comparatively small area south of Addis Ababa. The term Gurage therefore refers to a group of peoples with a common cultural and historical background who speak different South Ethiosemitic languages

Although Amharic is used as a *lingua franca*, it does not mean that the speakers of these endangered languages are shifting towards Amharic. Only speakers of some languages, for example, Geez (partly), Gafat, Argobba (partly), and Kimant, have shifted or are shifting toward Amharic. In some cases, the language shift is taking place towards other major languages such as Oromo (e.g., Anfillo). The language shift patterns vary and depend on various socioeconomic and demographic factors.

Ethiopian Semitic Languages

A Wetter, Johannes Gutenberg University, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

The Ethiopian Semitic (ES) languages form a subdivision of the Semitic language family that is a branch of the Afroasiatic superfamily. This subfamily comprises about 23 languages. Two languages (Tigre and Dahlik) are spoken only in Eritrea. Tigrinya (Tigrigna) is spoken in Eritrea and Ethiopia and all the others are in Ethiopia. (Unless otherwise specified, figures of speakers cited in this article are taken from the Ethnologue website.)

Classification and Demography

The still widely accepted classification of ES is based on shared "innovations due to internal reasons" (Hetzron, 1972: 13) and has two main divisions, a northern (NES) and a southern branch (SES). The northern group is formed by only four languages: the ancient Ge'ez (now extinct), Tigrinya (1 900 000 in Eritrea and 3 225 000 in Ethiopia), Tigre (800 000), and the recently identified Dahlik (1000) by Simeon-Senelle (2000). The southern branch, in contrast, comprises most of the languages and has a more complex composition, with several subgroups. This branch, according to Hetzron (1972), is classified into Transversal and Outer South ES. The languages forming the Transversal South ES are spoken in the central and center-eastern parts of Ethiopia and is subdivided into Central Transversal, consisting of Amharic (spoken as a first and second language by 80% of the 70 million total population of Ethiopia; cf. Meyer and Richter, 2003) and Argobba (10 000), and Eastern Transversal, consisting of the Eastern Gurage languages, i.e., Silt'e, Zay, and Wolane (together 900 000) and Harari (22 000), spoken in the city of Harar. The second subgroup, Outer South ES, contains all other languages that are divided into a 'n-group,' which consists of Gafat, a non-Gurage language that is extinct, and the North Gurage languages that comprise Goggot, Soddo (Gurage, Soddo), and, according to Leslau (1969) and Demeke (2001), Mäsqan, (together around 300 000) and a 'tt-group,' which comprises about nine different languages (Muher, Ezha, Chaha, Gumär, Gura, Gyeto, Ennemor, Endegen, and Endär, together 800 000). These languages are spoken in a comparatively small area south of Addis Ababa. The term Gurage therefore refers to a group of peoples with a common cultural and historical background who speak different South Ethiosemitic languages

that do not necessarily constitute a single genetic group.

The geographical origin of the ES languages is controversial. The traditional hypothesis proposes an origin in the Near East: Semitic-speaking settlers from Southern Arabia crossed the Red Sea and introduced the ancestor of modern ES languages in Northeast Africa around 1000 B.C. (cf. Ullendorff, 1955). In contrast, there is a more convincing hypothesis that sets the emergence of Semitic languages in the context of the Afroasiatic language family and proposes an origin in Ethiopia proper (cf. Murtonen, 1967; Drewes, 1958; Hudson, 1977, among others).

Phonology

Ejective consonants (p', t', s', c', and k') are widespread in all ES languages and seem to represent an earlier stage of Semitic emphatic consonants. Pharyngeal consonants are retained in NES, Argobba, and Harari but are lost in the remaining languages. Labialization, especially of velars, is common. Quite complex palatalization and labialization processes appear in several Gurage languages. Vowel length is attested only in Ge'ez and Eastgurage. The central vowel ɨ acts as an epenthetic vowel in many SES languages. Gemination of consonants is distinctive.

Morphology

The verbs are categorized in different types depending on the gemination of the penultimate consonant and the vowel quality in different conjugational paradigms. The different behavior of gemination in type A verbs is one of the distinguishing features between NES and SES languages. The former geminates in the perfective whereas the latter does so in the imperfective.

Verbal negation is marked by prefixed morphemes, which may differ for different aspects. In addition to the two main aspect forms, perfective and imperfective, there are a number of compound tense constructions formed with auxiliaries (build with the verb of existence √*hlw*). A special form of verbs are the so-called compound verbs. Their composition has the form ideophone + conjugated form of the verb 'to say'; the first carrying the semantic content and the latter the grammatical functions such as person or aspect.

The use of converbs for verbal subordination (expression of sequence or adverbial concept) is common. They appear generally in two different forms: In NES languages and Amharic/Argobba gerundive forms are used, whereas in the remaining SES languages there are a number of different suffixes attached to different verb forms such as perfective and imperfective.

The relative is marked with a morpheme that is prefixed to a verb that by itself precedes the head noun of the relative clause. Verbal derivation is achieved by prefixes and internal extension of the stem. Derivational prefixes are a- and as- for causative and t- for passive or middle voice.

Nominal morphology is characterized by the broken plural in NES languages and the use of suffixed plural markers in SES languages. In some languages this plural suffix marks the transnumeralis. An article derived historically from possessive marker can be observed in some languages. Marked cases are accusative, which is marked either by a pre- or by a suffix, and genitive, which is marked by position or with a prefix at the possessor that precedes the possessed.

Syntax

The most striking feature of ES language syntax is the word order, SOV, which stands in an obvious contrast to VSO in the Asian Semitic languages. This change of word order leads to a somehow mixed typological situation, i.e., the verb is in the sentence-final position and the subordinated clause precedes the main predication.

(1) lɛgan azzɛnnɛwga mɛt'ɨllɛw (Argobba)
tomorrow NEG.it-rained.if I-come
'If it doesn't rain I will come'

In addition to postpositions, which are typical for SOV, prepositions are widely used. Most of them are also used as conjunctions that are usually cliticized to the following constituent (t- and b- are more frequent; k-, s-, and l- are seldom used). The suffixed pronominal features for the direct object often have the form of affix, unlike those in Asian Semitic languages, which are clitics. The present tense copula is formed in many languages by the root nɛ- plus a person-marking suffix. Tigre and Ge'ez express present tense equative clauses without a copula or with a pronoun copula, as in most Asian Semitic languages (Crass *et al.*, 2004). The past tense copula in most ES languages is nɛb(b)ɛr. *Wh*-items are *in situ* types and question words may be used in yes–no interrogatives and usually have postverbal position. Relative forms of verbs are frequently used in nominal function.

On the discursive level, cleft sentences play a major role, especially for focusing of certain parts of a sentence.

(2a) tɛlantɛna nɛw sɛwɨyyɛw yɛmɛtt'aw (Amharic)
yesterday COP man-the REL.he-came
'It was yesterday that the man came'

(2b) sɛwɨyyɛw nɛw tɛlantɛna yɛmɛtt'aw
man-the COP yesterday REL.he-came
'It was the man that came yesterday'

Most of the morpho-syntactic differences between Ethiosemitic and Asian Semitic languages are assumed to be the result of language contact on the Ethiopian side, but there are not enough data to support this claim. Documentary works still need to be conducted on many of these languages.

This article has two main objectives. First, it describes the various ways in which ethnicity has been analyzed and the insights it sheds into an understanding of social and political processes. Second, and relying on data from Africa and the experiences of immigrant communities in Western countries, we analyze the relationship between ethnicity and language variation to explore the nature of the possible insights we might develop into ethnicity by studying ethnicity within Africa as well as in European and North American immigrant communities. The key contribution of this article is the way in which it illustrates how the relationship between ethnicity and language variation is more fruitfully understood not only when it is analyzed contextually, but also and more importantly when the analysis is embedded within the *longue durée* (Wallerstein, 2000). Wallerstein uses the French term *longue durée* to describe changes, social and political, which take place over a long historical period. This article will also examine how ethnic identities shift due to migration. Examining ethnicity within migration is necessary because of the massive voluntary and involuntary migration both within and from Africa to Europe and the United States. Our goal is to determine what it is about ethnicity which renders it susceptible to shift and manipulation.

While definitional details of ethnicity may vary from one discipline to another, the central tendency of ethnicity is how people define themselves *vis-à-vis* others, how distinctions are made between 'we' and 'they' (Newman, 1978: 105) or between 'us' and 'them.' Ethnicity is dynamic rather than enduring, fixed or unchanging. It is, as Jenkins (1997: 13) notes pointedly, collective and individual, externalized in social interaction and internalized in personal self-identification; it is situationally defined and is

This article has two main objectives. First, it describes the various ways in which ethnicity has been analyzed and the insights it sheds into an understanding of social and political processes. Second, and relying on data from Africa and the experiences of immigrant communities in Western countries, we analyze the relationship between ethnicity and language variation to explore the nature of the possible insights we might develop into ethnicity by studying ethnicity within Africa as well as in European and North American immigrant communities. The key contribution of this article is the way in which it illustrates how the relationship between ethnicity and language variation is more fruitfully understood not only when it is analyzed contextually, but also and more importantly when the analysis is embedded within the *longue durée* (Wallerstein, 2000). Wallerstein uses the French term *longue durée* to describe changes, social and political, which take place over a long historical period. This article will also examine how ethnic identities shift due to migration. Examining ethnicity within migration is necessary because of the massive voluntary and involuntary migration both within and from Africa to Europe and the United States. Our goal is to determine what it is about ethnicity which renders it susceptible to shift and manipulation.

While definitional details of ethnicity may vary from one discipline to another, the central tendency of ethnicity is how people define themselves *vis-à-vis* others, how distinctions are made between 'we' and 'they' (Newman, 1978: 105) or between 'us' and 'them.' Ethnicity is dynamic rather than enduring, fixed or unchanging. It is, as Jenkins (1997: 13) notes pointedly, collective and individual, externalized in social interaction and internalized in personal self-identification; it is situationally defined and is

produced (endlessly anew) in the course of social transactions that occur at or across (and in the process help to constitute) the boundary between ethnic collectivities (Jenkins, 1997: 52, 1994: 63, 198). Put differently, ethnicity is context-dependent; that is, it is 'brought about' rather than 'brought along' in an interaction and is activated in different ways in different contexts (Hinnekamp, 1982, quoted in Makoni, 1996: 268–269). At its core, says Fishman (1977: 17), "ethnicity is experienced as coming 'with the blood if not through it'; as an inherited constellation acquired from one's parents as they acquired it from theirs, and so on back further and further, *ad infinitum*." For some, to be without ethnicity is 'to be faced with one's death' (de Vos and Rmanucci-Ross, quoted in Fishman, 1977: 19). It is perhaps because individuals and groups feel so strongly about ethnicity that Fishman (1977: 18) warns that when we deal with ethnicity, "we may be dealing with some of the strongest assumptions and some of the most powerful investments in which social man is involved." Because of the wide range of disciplines studying ethnicity, as pointed out below, its meanings are generally ambiguous and multiple. Accordingly, we will be using the term ethnicity in a broader sense than that of Bourhis and Marhall (1999), who use it interchangeably with 'minorities' or ethnic people in America.

As already observed, ethnicity is currently being studied in a wide range of disciplines, prominent among them being political science, sociology, sociolinguistics, and more recently cognitive anthropology. It must be pointed out, however, that research into ethnicity is a recent 'vintage' (Brutt-Griffler and Davies, 2005). In academia there was a general tendency to shy away from studying ethnicity, particularly in Africa, since it was seen as a retrogressive and shameful topic that would not necessarily promote national interests and aspirations for integration. Against this background, the new nation-states in Africa sought to achieve national integration through 'erasing' (Irvine and Gal, 2000) ethnic identities (Kashoki, 2003). The quest for national integration, which was to prove illusory in Africa, was sought politically through a one-party state, and linguistically in language planning policies predicated upon a one nation = one language policy or what Bambgose (1991) calls a preoccupation with 'one.' In South Africa, for instance, ethnicity was construed as a false and divisive creation of the architects of apartheid. The idea of distinct ethnic groups with distinct languages formed the basis of the apartheid's homeland policy, or policy of separate development (Herbert, 1992), a policy that led to the creation of separate homelands for the various black ethnic groups. There was, for instance, a Zulu ethnic homeland for Zulu-speakers, a Xhosa homeland for Xhosa-speakers, a Ndebele homeland for Ndebele-speakers, a Swazi homeland for Swati-speakers, to name a few (Kamwangamalu, 2000) and despite the fact that the languages that these groups spoke were mutually intelligible varieties of the Nguni language. The idea of ethnicity as inextricably linked to language, indeed the idea of ethnicity as language, is a product of German Intellectual Romanticism (Cook, 2004). It is interesting to observe that although the idea of language as ethnicity was a product of early colonial period, most contemporary South Africans, for instance, associate standard Zulu with Zulu ethnicity, se Tswana language with seTswana ethnicity, isiXhosa with Xhosa ethnicity. The former homeland regimes of the apartheid era, which used the idea of language as ethnicity as one of their operational principles, overlooked the fact that the notion of language had longer roots traceable to early colonial thinking.

The earliest use of the term ethnicity as a way of framing research into social relations can be traced to Wallerstein's 1960 seminal article, 'Ethnicity and national integration in West Africa' (reprinted in Wallerstein, 2000: 3). In the article Wallerstein distinguishes ethnicity from tribalism. For him, ethnicity was largely an urban phenomenon arising in contexts in which there is an interplay between the ways in which individuals define themselves and how they are defined by others, much as we have pointed out earlier with respect to definitional details of ethnicity. Wallerstein argues that the new social relationships are more appropriately described not by the term ethnicity but by the French term *association d'originaires* (Wallerstein, 2000: 4). The French term did not, however, gain much currency in studies into ethnicity. Social relationships in tribes as opposed to ethnic groups were construed as heavily dependent upon a sense of loyalty to chiefs. Linguistically, social relations within an ethnic group are reinforced through the use of kinship idioms drawn from tribal relations: old ways of encoding new social relationships, so to speak. The distinction between tribalism and ethnicity that forms the basis of Wallstertein's early thinking about ethnicity is no longer necessary because the term tribalism has fallen into disrepute and has largely been superseded by ethnicity in most academic discussions. But has it entirely? Although the term tribalism has fallen into disrepute, it has not been completely excluded in serious discussions about ethnicity and identity and may be making a subtle comeback, as can be inferred from Joseph's (2004) concept of 'tribal language' and Mey and Modood's (2001) 'new tribalism,' a term akin to ethnic labels (see below) and one that Western

discourses use to describe the alleged socially disruptive effects of immigration by non-Westerners to Western countries.

Ethnicity and Ethnic Labels

Ethnic labels typically exist in a "context of oppositions and relativities" as when groups encounter other groups (Comaroff and Comaroff, 1996). For example, the ethnic label Shona was first used not by the Shona to describe themselves but by the Nguni-speaking Ndebele to refer to the Rozwi people they met after entering the Changamire state in the 1830 in southern Africa. If the Shona were being defined ethnically by the Nguni, they were defining themselves not linguistically, culturally, or ethnically, but politically – as "subjects of a particular chief" (Ranger, 1985). In the mid-20th century identities among the "Shona expanded beyond historical political units to be thought of as a matter of language, culture, and ethnicity" (Ranger, 1985), thus reflecting the point, made in Ross (1979: 9–10), that "language is probably the most powerful (though not necessarily the only one) symbol of ethnicity because it serves as a shorthand for all that makes a group special and unique."

Despite this, in the context of the Shona of Zimbabwe it was not always the case that there was a connection between ethnicity and language. The relationship between ethnicity and language is further complicated by the fact that although currently the Shona may define themselves linguistically as Shona, it does not follow that everyone who so identifies themselves does, *ipso facto*, consider themselves as Shona ethnically. For example, the Mozambicans who live in the Ndau region in southern Zimbabwe do not see themselves as Shona although they speak Ndau, a dialect which linguists would refer to as Shona (MacGonagle, 2002). Historically, the ancestors of Ndau speakers would not have identified themselves either as Ndau or Shona ethnically. They would rather have identified themselves politically as either subjects of Sanga or Teve (Beach, 1994) or some other local chief. Eldredge (1993) in a study of 19th century Lesotho provides another example that illustrates how ethnicity evolves over the *longue durée* (see also Atkinson, 1989 for an analysis of the evolution of ethnicity among the Acoli in Uganda). Eldredge describes how the emergence of Sotho ethnicity was a product of the amalgamation of southern African chiefdoms. These identities, which were clearly a product of a specific historical epoch, tend to be treated by the speakers as natural, essential, and primordial. For example, Yoruba-Ibo rivalry has played a key role in Nigerian politics, although the use of the term Yoruba itself to refer to western Nigeria was initially used by Anglican missionaries, and standard Yoruba was created to unify the diverse groups in western Nigeria (Wallerstein, 2000: 5).

There are two questions that arise when we focus on how ethnicity evolves historically. First, how do these identities emerge? Second, what is it about ethnicity that renders it so susceptible to manipulation? Common ethnic identities emerge when people perceive themselves as occupying a common cultural space, have a real or imagined common descent, or regulate their lives in comparable ways (Weber, 1978). As Le Page and Tabouret-Keller (1985) would put it, a common ethnic identity presupposes, for those who lay claim to it, shared culture and/or language, measure of consensus of the evaluation of others, active self-identification with the in-group, ascription to it by outsiders, and/or some idea of biological kinship and inheritances (see also Paden, 1970: 245).

Ethnicity and History

Historians have argued that the emergence of ethnicity as a form of identity was a product of colonialism. Tribalism in this line of reasoning, best illustrated by Vail (1989), was invented by colonialism. Colonialism fixed identities that were fluid in pre-colonial eras. Whether or not all ethnicity is a product of colonialism is increasingly being challenged. For example, Zulu ethnicity in South Africa may be more usefully traced back to Chaka even though it crystallized during the colonial era (Makoni and Meinhof, 2003).

Discussions on whether ethnicity can be traced to epochs other than the colonial era miss the point. The important issue that Vail's model of ethnic construction demonstrates is that ethnicity, even if it is subsequently treated as primordial, can be constructed and manipulated for political purposes by rulers irrespective of whether they are pre-colonial, colonial, or contemporary African rulers or elites. For instance, the colonial rulers in the former Belgian Congo, now the Democratic Republic of Congo, manipulated ethnicity to divide Ciluba-speakers into what came to be known as Bena-Lulua and ba-Luba, a division that led the country into a civil war in the early 1960s. Likewise, during his 32-year-rule over the Democratic Republic of Congo, a country he renamed Zaire, the late dictator Mobutu Sese Seko played one ethnic group against the others to maintain hs power.

This phenomenon of ethnicity manipulation can be observed in several other African states. In South Africa the apartheid regime played the ethnic card to divide the black population, and particularly to create tensions between the Inkatha Freedom Party, whose members are mostly Zulus, and the African

National Congress (ANC), which tends to be identified with the Xhosas. The ongoing political conflicts in Ivory Coast and the Sudan, for instance, have their roots in ethnicity, and so do the conflicts in Rwanda and Burundi, where the Tutsis and the Hutus have been at loggerheads with each other for generations. Listing these cases of ethnicity manipulation is not to say that ethnic constructions are monopolized by rulers and elites with the disadvantaged passively acquiescing. The disadvantaged and non-elites also at times challenge their social definitions as the other and outsiders (MacGonagle, 2002). Greene (1996) demonstrates how Anlo women in West Africa since the 17th century have exploited and shifted ethnic boundaries within the lineages of Anlo society in southeastern Ghana. Herbert (2002) reports on the linguistic behaviors of Mozambique Thonga men and women who migrated to South Africa generations ago. He shows how Thonga women, unlike Thonga men, resist abandoning their Thonga ethnicity for a Zulu ethnicity, despite the prestige that is associated with the latter. It is observed that while Thonga men universally speak Zulu and make a conscious effort to pass themselves as Zulu to improve their social and economic mobility, Thonga women do the opposite: they display their Thonga identity by speaking 'bad Zulu,' that is, Zulu replete with Thonga lexical residue as well as phonological and morphosyntactic influences (Herbert, 2002: 327). Herbert explains that Thonga women traditionally enjoy more status, privileges, and power than Zulu women. Accordingly, for Thonga women to embrace Zulu ethnicity as their men do would involve a marked diminution of their status and power (2002: 331). Eldredge (1994) documents how through marriage alliances women facilitated the spread of a common culture and language over a wide geographical area.

The observations by Greene and Eldredge (1994) are crucial. They foreground the importance not only of studying ethnicity and language historically, but of stressing the intersection between language, ethnicity, and gender relationships, which become clearer when studied over the *longue durée*. Epistemologically, studying the intersection between ethnicity and gender and language is an important departure, because gender and ethnicity have tended to be treated as separate fields in Western linguistics (Cameron, 1993). It is doubtful whether the separation is a viable way of proceeding when studying ethnicity in colonial and post-colonial contexts.

Ethnicity and Migration

Migration is increasingly playing an important role in shaping the nature of the relationship between ethnicity and language variation in contemporary Africa. An important post-independent trend in Africa is the massive migration of Africans from different ethnic groups to urban centers. Because of economic stagnation there are large numbers of unemployed youths as well as of people from different ethnic backgrounds living in close proximity. Therefore, investigating the potential effects of ethnicity on language variation becomes crucial. For example, in Bukavu the dominant center of the Kivu province situated at the southern tip of Lake Kivu in the Democratic Republic of the Congo, Goyvaerts (1996) reports that there are between 40 and 50 different languages in a population of about 240 000 people. In these contexts new forms of language emerge to express the new identities that are meant to mask previous ethnicities. The new language varieties tend to be hybrid languages and are generally used to neutralize the potentially negative effects of ethnicity (Goyvaerts, 1996). It is not clear whether these new forms of expression are best described as hybrid languages, registers, anti-languages, or stylistic inventories.

The crucial issue, however, is that these new forms of expressions draw from the social and linguistic landscape, in ways that complement existing languages. The ways in which the new expressions draw from the social and linguistic landscape may vary from one setting to another. In the Ivory Coast the linguistic expressions may draw liberally from French and other African languages. In urban South Africa the new urban expressions may draw from Afrikaans, English, and other local languages. For instance, in a study of the linguistic makeup of identity in an urban community in post-apartheid South Africa, Finlayson and Slabbert (2000) show that the free movement of communities coupled with the competitive forces of supply and demand has resulted in a hybrid form of identity, an identity that distinguishes urban people from their rural counterparts. This identity, the authors propose, is hybrid because it simultaneously embraces those features that are marked as 'modern' and 'Western' and those that are marked as 'traditional' and 'African' (Finlayson and Slabbert, 2000: 122). Although the new forms of expression of this hybrid identity may mask ethnic origin they tend to be gendered. For example, girls include more English in their speech while boys are likely to draw more liberally from Afrikaans, Tsotsitaal, and other local languages.

The new expressions in urban areas demonstrate that it is indeed possible for people to shift from one ethnic identity and appropriate a new form of urban identity. Current urban migrations in the Democratic Republic of Congo provide an excellent example of

the phenomenon of identity shift under discussion. With the collapse of the economy in the Democratic Republic of Congo the elites in non-industrial cities have migrated to industrial ones in search of job opportunities. The change of location has forced the migrants to effect a change in their ethnic identity by adjusting their speech to reflect that of their new environment. For instance, Ciluba speakers who migrate from Western Kasai to Eastern Kasai to work for MIBA, a major diamond company in the region, tend to adopt the local variety of Ciluba, one that is different from their native variety. Though both varieties are mutually intelligible, there are marked phonological differences in that where Western Kasai Ciluba, for instance, uses [p] as in *Mulopo* 'God', *kupesha* 'to give', *bupole* 'peace', Eastern Kasai Ciluba uses [h] so that it renders the above words as '*Muloho*', *kuhesha*, and *buhole*, respectively. For the migrants, the shift from Western Kasai Ciluba to Eastern Kasai Ciluba, and with it the shift of ethnic identity, is a strategic one aimed at facilitating access to whatever resources are available in the new environment.

Looking outside African culture for a moment, a further example of strategic shift in ethnicity comes from the naming practices by the Tuvans, an indigenous Turkic people of south central Siberia in the former Soviet Union. According to Harrison (1999: 69), the Tuvans maintain a tenuous identity, pummeled by forces of linguistic and cultural assimilation to the Russian culture on the one hand, and empowered by a discourse of self-determination on the other. Rather than assimilate completely to the Russian culture, the Tuvans adopted a symbiosis of Russian and Tuvan naming systems, a strategy that sought to restore the equilibrium by preserving the old (that is Tuvan) system (through retention of Tuvan kinship terms and nicknames) while accommodating the new one, that is the Russian naming system, which was imposed on them. Harrison explains that the Tuvans adopted the noted symbiosis because, on the one hand, the use of the Russian language and names provided access to cultural capital and advancement and, on the other hand, the mixture of the Russian naming protocols with the Tuvan ones (e.g., use of Tuvan nicknames and kinship terms) ensured that the adoption of the Russian naming system did not bring about the demise of the Tuvan culture and identity.

All the above examples attest to the point, made in several studies (Fishman, 1977; Okamura, 1981; Courteau, 1991; Jenkins, 1994), that language is generally seen as the most powerful symbol of ethnicity. The studies also note, however, that language is not always the sole medium through which ethnicity is expressed. A wide range of other media also serve as symbols of ethnicity, among them ethnic dress, dance, foods, and physical features, to list a few. For example, in Ghana 'original Accra' residents tend to refer to all merchants from the north as Hausa on the basis of geographical origin and professional status or what may be termed industrial ethnicity. Social geographers are increasingly beginning to demonstrate how space is used to imagine and construct ethnicity (Seirlis, 2004). In Abidjan, however, the same people may be referred to as Diola. In Zimbabwe, all people from Malawi irrespective of ethnic background are classified by Shona speakers as Chewa. Although these ethnic designations may have arisen in error, the Hausa/Diola/Chewa may take advantage of these new designations to merge into their new groups. In Accra the 'new' Hausa may end up living in Sobon Congo. In West Africa to facilitate their integration into the Hausa some of the migrants may convert to Islam, but not necessarily learn to speak Hausa as an additional language. Apparently, the conversion is a temporary one because upon return to the rural area they shift back to their previous religion (Wallerstein, 2000).

The pressures to shift away from an ethnicity-bound self construction and adopt another identity also takes place among Africans in the new diaspora in North America. Ibrahim (2003) describes how black Sudanese, when migrating from Sudan to North America, have to learn to imagine themselves as black within the North American space. In the North American context, as part of the process of learning to be black, they learn Black English Vernacular as an additional language. Black English Vernacular becomes a crucial marker of their new found black identity. The shift in this case is from an ethnic based identity to a racial one. This is achieved by learning Black English Vernacular, (*Whassup homeboy*) as expressed felicitously by Brutt-Griffler and Davies (2005) when she describes it as a shift from being American African to African Americans.

Census, Language, and Ethnicity

An important strand in ethnic and identity formation has relied on censuses. Inspired by the work of Bourdieu, this literature has sought to examine how censuses tend to create people by "nominating into existence" new categories (Brubaker *et al.*, 2004). An analysis of the categories used in the censuses is important in so far as it sheds insight into the categories being used by government. For example: an analysis of the census categories used by the Southern Rhodesian government in 1926 and the Zimbabwean

Government in 1982 and in 1992 provides empirical evidence on how colonial and postcolonial governments understood the nature of the relationship between ethnicity and language.

> 1926
> Form for the use of EUROPEANS or WHITE PERSONS only
> A separate form must be filled in for each Family or Household. If one form is insufficient, please ask for Additional Forms. All Europeans or White Persons, including visitors, lodgers and white servants, whether in the main building or outside rooms, to be entered hereunder. Particulars about Asiatic, Coloured, or native Servants or Employees residing in this Dwelling or on the Premises must be given on the separate forms provided for those persons.

In the 1926 census there was no distinction made between the different European groups. It was insignificant how the colonial state imagined Europeans, whether they were Dutch, Portuguese, Greek, or English. Similarly, no distinctions were made within the Asian group. Both Europeans and Asians were distinguished from 'Coloured' and native Servants (Africans). Africans were largely seen in terms of employees. African employees had to be distinguished from white employees on the basis of race. There was no explicit mention of ethnicity.

In the 1982 census, which was the first census Zimbabwe conducted after it attained independence in 1980, the labels or categories used to identify the different population groups changed. The concept of ethnicity emerges:

> ETHNIC GROUP and CITIZENSHIP
> Is this person a Zimbabwean? Zimbabwean Africans state father's dialect.
> Other Zimbabweans state ethnic group. Others state citizenship and ethnic group.

The categories in the 1982 census differ radically from the 1926 one. In the 1982 census the distinction is now made between Zimbabwean Africans and other Zimbabweans. The other Zimbabweans are likely to be Europeans, 'Coloured,' and Asians if we are to use the categories in the 1926 census. Ethnicity only needs to be stated for non-Zimbabweans but not for Zimbabweans. Ethnicity for Zimbabwean Africans is only assessed by proxy via the 'father's dialect.' Asking about the father's dialect was therefore a euphemistic way of enquiring about the nature of the relationship between ethnicity and language. It is instructive that the form asked for the father's dialect and not the mother's.

In the 1992 census a new set of questions were asked.

> What is the name's ethnic origin?
> 1. African
> 2. European
> 3. Asiatic
> 4. Mixed race

In the 1992 census yet other categories emerge. The differences between Zimbabwean Africans and other non-African Zimbabweans are now expressed in terms of a distinction between African and European. The distinction made in the 1982 census between Zimbabwean Africans and other Africans has disappeared. Both groups are now replaced by a simple category, namely, Africans. It's important to observe that from the 1926 census through to the 1992 census the category that has been retained continuously through the different censuses is that of Asiatic and 'Coloured,' with 'Coloured' at times being used instead of 'mixed race.' An analysis of these categories is important because they may have profound consequences on how individuals understand themselves. Further studies are required into how popular understandings relate to the official accounts of ethnic categories.

Conclusion

In this article we have analyzed the nature of the relationship between ethnicity and language, with a focus especially on Africa. We have tried to illustrate the various ways in which ethnicity might be conceptualized, and the social and political roles it might play in shaping individual and collective identities. We have argued that at least in Africa and perhaps among ethnic minorities in the United States and Europe, it might be prudent to adopt a long term perspective on the nature of the relationship between ethnicity and language. It might also be necessary to conflate distinctions between ethnicity and gender rather than studying them as separate areas, as has traditionally been the case.

Ethnolinguistic Vitality

Objective Group Vitality

Linguists and sociolinguists concerned with issues of language contact, multilingual communication, language attitudes, bilingualism, language shift, and language loss must inevitably deal will the relative strength and weaknesses of the language communities they are investigating. Sociostructural and sociopolitical factors can fundamentally affect the nature and quality of 'intergroup' contact between speakers of contrasting ethnolinguistic groups (Bourhis, 2001a). The concept of 'ethnolinguistic vitality' emerged out of the critical need for situating the sociolinguistic and social psychological processes underlying language behaviors within their proper sociostructural contexts (Johnson *et al.*, 1983).

The notion of ethnolinguistic vitality provides a conceptual tool to analyze the sociostructural variables affecting the strength of language communities within multilingual settings. The vitality of an ethnolinguistic group is defined as "that which makes a group likely to behave as a distinctive and collective entity within the intergroup setting" (Giles *et al.*, 1977: 308). The more vitality an ethnolinguistic group has, the more likely it is that it will survive and thrive as a collective entity in the intergroup context. Conversely, ethnolinguistic groups that have little or no vitality are more likely to eventually cease to exist as distinctive language groups within the intergroup setting.

Three broad dimensions of sociostructural variables influence the vitality of ethnolinguistic groups: demography, institutional support, and status. Demographic variables are those related to the absolute number of members composing the language group and their distribution throughout the urban, regional, or national territory. Number factors refer to the language community's absolute group numbers, their birth rate, mortality rate, age pyramid, endogamy/exogamy, and their patterns of immigration and emigration in and out of the ancestral territory. Distribution factors refer to the numeric concentration of speakers in various parts of the territory, their proportion relative to 'outgroup' speakers, and whether or not the language community still occupies its ancestral territory. These demographic factors can be based on one or a combination of the following linguistic indicators: L1 as mother tongue, knowledge of a first (L1) or second (L2) language, L1 and/or L2 language use at home. Taken together, these indicators can be used to monitor demolinguistic trends such as language maintenance, language shift, language loss and inter-generational transmission of the L1 mother tongue. Within democracies, demographic factors constitute a fundamental asset for ethnolinguistic groups, as 'strength in numbers' can be used as a legitimizing tool to grant language communities with the institutional control they need to ensure their inter-generational continuity within multilingual societies.

Institutional control is defined as the degree of control one group has over its own fate and that of outgroups, and can be seen as the degree of social power enjoyed by one language group relative to salient outgroups (Sachdev and Bourhis, 2001). Institutional control is the dimension of vitality par excellence, needed by language groups to maintain and assert their ascendancy relative to competing language groups. Conversely, subordinated language groups need to achieve and maintain a favorable position on the institutional control front if they wish to survive as distinctive collective entities within multilingual states (Fishman, 2001). The extent to which a language group has gained formal and informal representation in the institutions of a community, region, state, or nation constitutes its institutional support. Informal support refers to the degree to which a language community has organized itself as a pressure group to represent and safeguard its own language interests in various state and private domains. Formal support refers to the degree to which members of a language group have gained positions of control at decision-making levels of the government apparatus, in education, in health care, in the army, in business, industry, the mass media and within cultural, sport and religious institutions.

Status language planning adopted by regional or national governments can also contribute to the institutional support of language communities by legislating the use of competing languages in the government administration, in education, in the mass-media and as the language of work. The presence and quality of leaders who can head the formal and informal institutions representing language groups also contributes to the institutional control of language communities. Gains in institutional control often depend on the emergence of activists and leaders who succeed in mobilizing language groups to struggle for greater institutional control within multilingual states. The absence of quality leadership can undermine gains achieved by previous generations of group members on the institutional control front and can mortgage

future gains needed for the language survival of the next generation of group members. Taken together, language groups which have gained strong institutional control within state and private institutions are in a better position to safeguard and enhance their collective language and cultural capital than language communities who lack institutional control in these domains.

Language groups that have gained ascendancy on institutional support factors are also likely to benefit from considerable social status relative to less dominant groups within multilingual states. The status variables are those related to a language community's social prestige, its sociohistorical status within the state, and the prestige of its language and culture locally, nationally, and internationally. The more status a language community is ascribed to have, the more vitality it is likely to possess as a collectivity. Social psychological evidence shows that speakers of high-status groups enjoy a more positive social identity and can more readily mobilize to maintain or improve their vitality position within the state (Giles and Johnson, 1987). Conversely, being a member of a disparaged low-status linguistic group can sap the collective will of minorities to maintain themselves as distinctive language communities leading to linguistic assimilation. The experience of belonging to a high- vs. low-status language community is more vivid to the degree that status differentials between ethnolinguistic groups are perpetuated through language stereotypes (Ryan *et al.*, 1982) and/or are enshrined through the adoption of language laws that legislate the relative status of language communities within multilingual states (Bourhis, 1984, 1994).

The above three dimensions combine to affect in one direction or the other the overall strength or vitality of ethnolinguistic groups (Giles *et al.*, 1977). A language group may be weak on demographic variables but strong on institutional support and status factors, resulting in a medium vitality position relative to a language minority weak on all three vitality dimensions. Language communities whose overall vitality is strong are more likely to survive as distinctive collective entities than groups whose vitality is weak within the multilingual setting. Demolinguistic and sociographic data based on the census and other sources are used to assess the relative vitality of ethnolinguistic groups within a particular multilingual setting. Such objective assessments of vitality do serve the descriptive and analytic functions needed to more rigorously compare and contrast the ethnolinguistic groups one is dealing with in linguistic and sociolinguistic research. The objective vitality framework was used to describe the relative position of language groups in numerous bilingual and multilingual settings such as: the French and the English of Quebec (Bourhis, 2001b), the Cajuns in Louisiana (Landry *et al.*, 1996), Hispanics in the United States (Barker *et al.*, 2001), the Catalan in Spain (Atkinson, 2000; Ytsma *et al.*, 1994), and ethnolinguistic groups in Nigeria (Mann, 2000).

Subjective Perceptions of Group Vitality

How speakers perceive the vitality of their own language community relative to salient linguistic outgroups may be as important as objective assessments of group vitality based on demolinguistic and census data. The subjective vitality questionnaire (SVQ) was designed to measure group members' assessments of 'ingroup'/outgroup vitality on each of the items constituting the demographic, institutional support, and status dimensions of the objective vitality framework (Bourhis *et al.*, 1981). A review of the vitality research using the SVQ showed that that overall, group members are realistic in perceiving their vitality position along the lines suggested by objective assessments of ethnolinguistic vitality (Harwood *et al.*, 1994). However, studies have also shown that ethnolinguistic group members can be biased in their assessments of 'owngroup' and outgroup vitalities. Such biases do not emerge on obvious differentials between ingroup/outgroup vitality, but are documented on objectively minor vitality differences between contrasting language communities.

Three basic types of subjective vitality biases were identified based on our review of the literature (Harwood *et al.*, 1994). Perceptual distortions in favor of ingroup vitality occur when language groups exaggerate the strength of their owngroup vitality while underestimating the vitality of the outgroup. Perceptual distortions in favor of outgroup vitality involve language groups who underestimate the vitality of their owngroup while exaggerating the vitality of the outgroup. Nonconsensual vitality perceptions occur when language groups disagree not only on the degree of difference between groups, but also on the direction of such difference. Both motivational (ingroup bias) and cognitive factors (availability and vividness heuristics) help account for these perceptual distortions of group vitality (Sachdev and Bourhis, 1993).

Empirical studies have also show that the vitality items listed within each dimension of the objective vitality framework are not necessarily perceived as falling within the demographic, institutional, and status dimensions of the model. Vitality items are perceived as belonging to configurations of dimensions that reflect current harmonious or problematic relations between language communities within

specific cultural settings. Noting such trends, Giles pointed out that "vitality is not a static given but, rather, a malleable social construction depending on social group membership and fluctuating socio-political circumstances" (2001: 473). Overall, studies show that perceivers are quite sensitive to the relative position of their own language group relative to outgroups on each vitality element making up the three dimensions of objective and subjective vitality.

Subjective Vitality as a Predictor of Language Attitudes and Behaviors

A basic premise of the subjective vitality framework is that group members' subjective assessment of ingroup/outgroup vitality may be as important in determining language attitudes and behaviors as the group's objective vitality (Bourhis *et al.*, 1981). A combination of both objective and subjective vitality information constitutes a more sensitive method of predicting the language behavior of group members than simply relying on objective assessments of group vitality (Giles and Johnson, 1987). Studies combining features of objective and subjective vitality have shown that ethnolinguistic vitality is related to a broad range of language attitudes and language behaviors. For instance, studies have shown that ethnolinguistic vitality was related to: self-reports of French language use in everyday activities by Acadians in New Brunswick (Landry and Allard, 1994), self-reported Turkish usage among immigrants from Turkey in France (Yagmur and Akinci, 2003), self-reported use of Bengali and attitudes to English use by Sylheti-Bangladeshi pupils in London (Lawson and Sachdev, 2004), evaluative reactions to language switching in Montreal and Quebec City (Genesee and Bourhis, 1988), positive/negative attitudes towards outgroups among blacks and Afrikaans-speaking whites in South Africa (Bornman and Appelgryn, 1997), Anglo-American support for the English only movement in the United States (Barker and Giles, 2004), ingroup favoritism attitudes by Castillians and members of the bilingual communities of Spain (Ros *et al.*, 1994), Francophone and Anglophone language competence in L2, willingness to communicate, and linguistic identity in Ontario (Clément *et al.*, 2003; Noels and Clément, 1996), and presence of French linguistic landscape perceived by Francophones across Anglo-Canada (Landry and Bourhis, 1997).

While the SVQ monitors general beliefs about the perceived vitality of ingroup/outgroup language communities (Bourhis *et al.*, 1981), the Beliefs on Ethnolinguistic Vitality Questionnaire (BEVQ) monitors egocentric beliefs, made-up of self-beliefs and goal beliefs concerning ingroup/outgroup vitality (Allard and Landry, 1986). While group members may perceive that their language community is weak on most vitality factors as per SVQ ratings, BEVQ ratings may show that most group members may do little personally to assert their own group vitality (self-beliefs) and may have no intention to act in favor of improving their owngroup vitality (goal beliefs). In contrast, other group members may also perceive that their owngroup vitality is weak but may endorse self- and goal beliefs in favor of bolstering their owngroup vitality on strategic institutional, demographic, and status factors. Thus a combination of general beliefs (SVQ) and egocentric beliefs (BEVQ) may better predict language attitudes and behaviors in multilingual settings. Allard and Landry (1994) compared the predictive value of their BEVQ with the SVQ, which they had administered to a large sample of Francophone minorities across Canada. Though their results showed that the BEVQ was the more powerful predictor of French language behavior, strong support in favor of the SVQ as a predictive measure was also obtained.

The concept of ethnolinguistic vitality has provoked debates, some of which have been addressed conceptually and empirically in the literature (Hamers and Blanc, 2000; Husband and Khan, 1982; Johnson *et al.*, 1983). To the degree that ethnolinguistic group members accurately perceive the vitality of their own group and that of salient outgroups, the SVQ can be used as a descriptive measure that can help validate the choice of ethnolinguistic groups used by researchers to conduct their sociolinguistic and social psychological studies. Combining objective and subjective vitality can be used as a tool of social analysis for addressing a broad range of empirical and theoretical issues related to language behaviors within both the linguistic, sociolinguistic and intergroup literature.

Ethnologue

G F Simons and R G Gordon Jr, SIL International, Dallas, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

Ethnologue: Languages of the World is a reference work cataloging all known languages of the present-day world. Now in its 15th edition (2005), the *Ethnologue* identifies 6912 living languages, both spoken and signed. These are distinct languages that have living mother tongue speakers. A few hundred recently extinct languages are documented as well.

For over 50 years, the *Ethnologue* has been compiled and published by SIL International, a nonprofit, nongovernmental organization that studies, documents, and assists in developing the world's lesser-known languages. Information comes from a variety of sources including reliable published sources, a network of field correspondents, and numerous personal communications that are confirmed by consulting published sources or the network of correspondents. The editorial staff processes approximately 10 000 updates to the database every year.

History of the *Ethnologue*

The *Ethnologue* was founded by Richard S. Pittman, who was motivated by the desire to share information on language development needs around the world with his colleagues in SIL International as well as with other language researchers. The first edition in 1951 was 10 mimeographed pages and included information on 46 languages or groups of languages. Maps were first included in the 4th edition (1953). The publication transitioned from mimeographed pages to a printed book in the 5th edition (1958). Dr. Pittman continued to expand his research through the 7th edition (1969), which listed 4493 languages.

In 1971, Barbara F. Grimes became editor. She had assisted with the *Ethnologue* since 1953 (4th edition) and took on the role of research editor in 1967 for the 7th edition (1969). She continued as editor through the 14th edition (2000). In 1971, information was expanded from primarily minority languages to encompass all known living languages of the world. Between 1967 and 1973, Ms Grimes completed an in-depth revision of the information on Africa, the Americas, the Pacific, and a few countries of Asia. During her years as editor, the number of identified languages grew from 4493 to 6809, and the information recorded on each expanded so that the published work more than tripled in size.

The 15th edition (2005) was edited by Raymond G. Gordon, Jr. It reflects an increase of 103 languages over the previous edition. Most of these are not newly discovered languages, but are ones that had been previously considered dialects of another language.

The Problem of Language Identification

Given the nature of language and the various perspectives brought to its study, it is not surprising that a number of issues prove controversial. Of preeminence in this regard is the definition of 'language' itself. Since languages do not have self-identifying features, what actually constitutes a language must be operationally defined. That is, the definition of language one chooses depends on the purpose one has in identifying a language. Some base their definition on purely linguistic grounds. Others recognize that social, cultural, or political factors must also be taken into account.

Every language is characterized by variation within the speech community that uses it. The resulting speech varieties are more or less divergent from one another. These divergent varieties are often referred to as dialects. They may be distinct enough to be considered separate languages or sufficiently similar as to be considered merely characteristic of a particular geographic region or social grouping within the speech community. Scholars do not all share the same criteria for what constitutes a 'language' and what features define a 'dialect.' The *Ethnologue* applies the following basic criteria:

- Two related varieties are normally considered varieties of the same language if speakers of each variety have inherent understanding of the other variety at a functional level (that is, can understand based on knowledge of their own variety without needing to learn the other variety).
- Where spoken intelligibility between two varieties is marginal, the existence of a common literature or of a common ethnolinguistic identity with a central variety that both understand can be a strong indicator that they should nevertheless be considered varieties of the same language.
- Even where there is enough intelligibility between varieties to enable communication, the existence of well-established distinct ethnolinguistic identities can be a strong indicator that they should nevertheless be considered to be different languages.

Increasingly, scholars are recognizing that languages are not always easily treated as discrete isolatable units with clearly defined boundaries between them. Rather, languages are more often continua of features that extend across both geographic and social space. The *Ethnologue* approach to listing

and counting languages as though they were discrete, countable units does not mean to preclude a more dynamic understanding of the linguistic makeup of the countries of the world. In fact, particular language entries in the *Ethnologue* list known dialects and often comment on the similarity and intelligibility relationships among them. In the final analysis, however, the *Ethnologue* lists and counts languages as distinguished by the criteria named above because it serves as a baseline for those who are developing language policy and making plans for language development. It is also foundational for those, such as librarians and archivists, who would classify written and spoken materials with respect to the languages they are in, or would organize pieces of language-related information with respect to the languages they are about.

Three-Letter Language Identifiers

A distinctive feature of the *Ethnologue* over the years has been its use of three-letter codes to uniquely identify the languages of the world. Any enterprise that would categorize language-related resources so that others might effectively retrieve those resources depends on the uniform identification of the languages to which they pertain. Simply using language names for this purpose is not adequate since the same language is typically known by many names and those names change over time. Furthermore, different languages may be known by the same name. Thus, the most effective approach is to use standardized language identifiers.

Standardized language identifiers were introduced into the *Ethnologue* in 1971 by then consulting editor, Joseph E. Grimes, when he transformed the typesetting tapes for the 7th edition (1969) into a computerized database on languages of the world. The work was done at the University of Oklahoma under a grant from the National Science Foundation. In 1974, the database was moved to a computer at Cornell University where Dr Grimes was professor of linguistics; it was moved to a personal computer in 1979. Since 2000, it has been housed at the headquarters of SIL International in Dallas, Texas.

One feature of the database since its inception has been a system of three-letter language identifiers. Grimes explained this feature as follows in the 1974 final report for the grant: "Each language is given a three-letter code on the order of international airport codes. This aids in equating languages across national boundaries, where the same language may be called by different names, and in distinguishing different languages called by the same name." While the codes were used behind the scenes in the database that generated the 8th and 9th editions, it was not until the 10th edition (1984) that they appeared in the publication itself.

The 15th edition (2005) marked an important milestone in the development of the language identifiers, namely, their emergence as a draft international standard. In 1998, the International Organization for Standardization adopted ISO 639-2, its standard for three-letter language identifiers. That was based on a convergence of ISO 639-1 (its earlier standard for two-letter language identifiers adopted in 1988) and of ANSI Z39.53 (also known as the MARC language codes, a set of three-letter identifiers developed within the library community and adopted as an American National Standard in 1987). The current standard, ISO 639-2, has proven insufficient for many purposes since it has identifiers for fewer than 400 individual languages. Thus, in 2002, ISO TC37/SC2 invited SIL International to participate in the development of a new standard based on the language identifiers in the *Ethnologue*. The new standard was to be a superset of ISO 639-2 that would provide identifiers for all known languages. Consequently, hundreds of the *Ethnologue* language identifiers were changed in order to achieve alignment with ISO 639-2. In 2004, the proposed new standard, ISO 639-3, passed the first round of balloting by national standards bodies to attain the status of Draft International Standard. The three-letter language identifiers in the 15th edition of the *Ethnologue* are thus the codes of ISO/DIS 639-3.

Endangered Languages

Language endangerment is a serious concern to which linguists and language planners have turned their attention in the last decade. For a variety of reasons, speakers of some languages are motivated to stop using their language and to use another. Parents may begin to use only that second language with their children. Eventually there may be no speakers who use the language as their first or primary language and frequently the language ceases to be used altogether and the language becomes extinct – existing, perhaps, only in recordings or written records and transcriptions. The concern about language endangerment is centered, first and foremost, around the factors that motivate speakers to abandon their language and the consequences of language death for the community of (former) speakers of that language. Since language is closely linked to culture, loss of language almost always is accompanied by social and cultural disruptions as well. Secondarily, those concerned about language endangerment recognize the implications of the loss of linguistic diversity,

both for the linguistic and social environment generally and for the academic community, which is devoted to the study of language more specifically.

There are two dimensions to the evaluation and characterization of endangerment: the number of speakers of the language and the number and nature of the domains in which the language is used. A language may be endangered because there are fewer and fewer people who speak that language. It may also, or alternatively, be endangered because it is being used for fewer and fewer functions. The *Ethnologue* attempts to provide data on both of these dimensions whenever it is available.

Language endangerment is a matter of degree. At one end of the scale are languages that are vigorous and perhaps are even expanding in numbers of speakers or functional areas of use. At the other end are languages that are on the verge of extinction. In between are many degrees of greater or lesser endangerment. The *Ethnologue* does not attempt to identify the level of endangerment of each language listed but does specifically identify those languages at the far end of the scale by indicating 'nearly extinct' at the end of the language entry. A language is listed as nearly extinct when the speaker population is fewer than 50 or when the number of speakers is a very small fraction of the ethnic group. In the 15th edition, 497 languages are so designated.

How to identify the level of endangerment of the remaining languages that are not designated as nearly extinct is not necessarily clear. Linguists seek to identify trends in language use, such as a decrease in the number of speakers or a decrease in the use of the language in certain domains or functions. An increase in bilingualism, both in the number of bilinguals and in their proficiency levels, is often associated with these trends. When data are available, the following factors that may contribute to endangerment are reported in the language entries: small population size, bilingualism, urbanization, modernization, migration, industrialization, the function of each language within a society, and whether or not children are learning it. Such factors interact within a society in dynamic ways that are not necessarily predictable. As a scholarly consensus forms that can be applied worldwide, a scale of endangerment is becoming increasingly possible. In the meantime, only brief statements about the above factors are given for each language as data becomes available.

Overview of Contents

The *Ethnologue* begins with an 'Introduction' and 'Statistical Summaries.' The latter give a summary view of the world language situation in terms of numerical tabulations of living languages and number of speakers by world area, by language size, by language family, and by country. Then follows the main body of the work in 'Part 1: Languages of the World.' This section provides detailed information on all known living languages of the world organized by area and by country. An extensive bibliography is located at the end of this section. 'Part 2: Language Maps' provides 208 color maps locating the languages in most countries of the world. Finally, 'Part 3: Indexes' consists of three indexes: a language name index listing all of the 39 491 distinct names that are associated with the languages described in Part 1, a language code index listing all of the three-letter language identification codes that are used in Part 1, and a country index listing the pages on which the section for that country begins in Part 1 and Part 2.

In Part 1, languages are listed by country under the five major geographic areas of Africa, the Americas, Asia, Europe, and the Pacific. The entry for a country begins with a header giving summary information about the country including official name, total population, a listing of national or official languages, a listing of recent immigrant languages, country literacy rates, and a count of languages indigenous to the country. This header is followed by an entry for each language of the country that is not a recent immigrant.

Entries are alphabetized by the primary name of the language. This is followed by all known alternate names and the three-letter identification code. An estimate of the speaker population is then given; there may also be an estimate of monolingual speakers, or of the size of the ethnic group (including those who no longer speak the language). Next, the location of the language group within the country is described, followed by the genetic classification of the language. Where dialects are known to exist, these are listed along with alternate names. Comments on intelligibility and similarity relationships among dialects or with neighboring languages may follow. Next are notes on language use, including functions of the language (such as official language or language of wider communication), viability, domains of use, age range of speakers, attitudes toward the language, and bilingual proficiency in other languages. These are followed by notes on the status of language development, including literacy rates, use in elementary or secondary schools, scripts used for writing, existence of published literature, and use in media. The entry closes with information in miscellaneous categories including general

remarks, linguistic typology, geological and ecological environment, subsistence type of the speakers, and religions.

Ethnomethodology

G Psathas, Boston University, Boston, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Ethnomethodology represents a new dimension, perspective, and approach in the social sciences and undertakes to study the everyday world as an achieved social reality. Its position is that all human action is irremediably indexical and reflexively related to the occasions and settings within which it occurs. Members are continually engaged in making sense, achieving intelligibility, and providing, for themselves and others, accounts of the self-same actions and utterances that, in turn, constitute the social situation in which they find themselves. Ethnomethodology proposes that the serious study of how members produce, sustain, achieve, and maintain 'the social world' requires close attention to the methods (i.e., members' methods, or ethno-methods) of that production, achievement, and maintenance, and these methods include all manner of practical reasoning and practical actions. The discovery, description, and analysis of such methods constitute ethnomethodology's main tasks.

Major Figures and Contributors

Harold Garfinkel, the founding father of ethnomethodology (who received his Ph.D. from Harvard in 1952), was concerned with the problem of social order. His position can be considered a radical counterposition to that of Talcott Parsons, a major theorist in American mid-20th-century sociology and an advocate of positivist, structural functional analysis and abstract theorizing as set forth in his book *The social system* (1950), with its pattern variables, and in his general theory of social action.

Garfinkel was influenced by his readings of the German phenomenologist philosopher Edmund Husserl and the sociologist and phenomenological philosopher Alfred Schutz, as well as by Aaron Gurwitsch, phenomenologist and psychologist, and by the French phenomenological psychologist and philosopher Maurice Merleau-Ponty.

Garfinkel worked most closely over a period of more than 12 years with Harvey Sacks. Their collaboration was extensive and one of mutual influence. Sacks (who died in 1975) went on to develop, with Emanuel Schegloff and Gail Jefferson, what has come to be known as conversation analysis, now considered to be one of the important offshoots of ethnomethodology. This field continues to be developed by Emanuel Schegloff, at the University of California, Los Angeles, Gail Jefferson, now in the Netherlands, and many other researchers in the United States and throughout the world.

Other contributors in America include E. Bittner, D. Bjelic, D. Boden, D. Bogen, S. Clayman, J. Coulter, C. and M. H. Goodwin, J. Heap, J. Heritage, S. Jacoby, P. Jalbert, G. Lerner, K. Liberman, M. Lynch, D. Macbeth, D. Maynard, M. Pollner, A. Pomerantz, G. Psathas, A. B. Robillard, A. Rawls, J. Schenkein, J. Streeke, L. Suchman, D. Sudnow, D. L. Wieder, T. Wilson, and D. Zimmerman.

Ethnomethodology spread to the United Kingdom, in part influenced by the visits of Garfinkel to Manchester, Aaron Cicourel to the University of London and Manchester in the early 1970s, Jefferson to Manchester (1979–1981) and York (1982–1985), and Anita Pomerantz to Oxford (1981–1984). British sociologists who have been most active have been R. J. Anderson, J. M. Atkinson, G. Button, R. Dingwall, P. Drew, D. Francis, C. Heath, S. Hester, J. Hughes, I. Hutchby, W. W. Sharrock, and D. R. Watson.

Other prominent names in ethnomethodology include P. Eglin, J. O'Neill, D. Smith, R. Turner and P. Weeks in Canada; C. Baker, E. Livingston, A. McCoul, and M. Nevile in Australia; J. Bergmann, M. Egbert, S. Hirschauer, K. Knorr, and S. Wolff in Germany; M. Barthélemy, B. Bonu, B. Conein, A. Coulon, M. de Fornel, Y. LeCerf, L. Mondada, L. Queré, and M. Relieu in France; H. Houtkoop-Steenstra, M. Komter, H. Mazeland,

remarks, linguistic typology, geological and ecological environment, subsistence type of the speakers, and religions.

Peräkylä, and M. Sorjonen in Finland; G. Fele, I. Paoletti, and L. Zapulli in Italy; and others around the world.

The Name 'Ethnomethodology'

The ethnomethodological approach studies the methods actually used by members of society for doing whatever it is they are doing, including their ways of talking about their activities.

A serious and careful study of the methods used by members for accomplishing practical actions in the world of everyday life would result in descriptions and analyses of the methodology of everyday life or of the ethno (the group's) methodology, or members' methods.

When Garfinkel first developed the term, he was studying how the members of a jury performed the task of jurying. But rather than refer to members' methods for doing jury work as ethno-jurying or ethno-law, which would provide subdivisions of members' methods according to the (substantive) topics with which their activities were concerned, he took a broader perspective.

Perhaps ethnosociology or 'members' ways of doing sociology' would have been alternative terms. But actually these terms would not be consistent with Garfinkel's intended topic of study, which is how members accomplish social order, not how members describe or analyze their society.

For example, in anthropology there had developed a perspective called ethnoscience, which aimed to discover the ways that members of a particular culture name and classify objects and products, that is, ethnobotany, ethnomusicology, ethnohistory, and so on, or in other words, the particular classification systems of particular cultures at particular times and places.

As Garfinkel stated (1967: 8), his concern was

> the *how* it [society] gets put together; the how it is getting done; the how to do it; the social structures of everyday activities.... studying how persons, as parties to ordinary arrangements, use the features of the arrangement to make for members the visibly organized characteristics happen.

Another way of saying this is that he was concerned with 'everyday praxis.'

The 'methodology' part of the term ethnomethodology is to be understood as referring to the 'how,' the actual situated practices, the methods by which everyday activities are accomplished.

However, members of society cannot simply be asked how they accomplish their everyday activities and their answers then used as propositional knowledge. The reasons offered are, firstly, that members are essentially not interested in analyzing how they do things; they are only interested in doing them.

Secondly, members are not aware, in any explicit sense, of how they do things. Therefore, even if asked to try to explicate, or analyze, what they do, their analyses are inadequate.

For members of society, the effective test of whether they know how to do something is whether they can actually do it, whether it be to have a conversation, draw a map, give directions, diagnose a disease, or give a lecture. Members operate with certain assumptions, take matters for granted, know how to do things without ever analyzing the 'how' of what they know, i.e., without ever having propositional knowledge.

For the ethnomethodologist, the methods that members actually use to accomplish whatever it is they are doing are an 'awesome mystery' (Garfinkel, 1967: 35). The discovery and explication of these methods are tasks for someone with a special interest, whose focus of attention will be on such matters directly.

If the social scientist is to analyze commonsense understandings, simply using the same commonsense understandings that members use will not achieve the desired result. Instead, the commonsense understandings must themselves be analyzed and made into topics of study, not simply used as resources for producing descriptions.

Ethnomethodology proposes to analyze commonsense knowledge and to discover how commonsense knowledge comes to be constituted; what produces, for members, the sense that it is knowledge; and how this knowledge is used. For Garfinkel, knowledge is not in the head but consists of the doing; i.e., knowledge is not a mentalistic phenomenon but praxis. (A knowledge claim is a claim; knowing how to do something is demonstrable only in the doing itself.)

However, social scientists cannot escape using commonsense knowledge (and understandings) in their own work. After all, they live in the world of everyday life, and they talk, write, and communicate using the same language and linguistic practices as members do.

Their own use of talk (language) can also be examined to discover the methods whereby talk makes 'visible' the matters talked about. Such methods as 'citation of typical cases,' 'referencing behavior to rules,' 'glossing,' and 'making arguments as to reasonableness,' among others, may be used by members and social scientists alike.

Such methods, because they are used by social scientists, are not somehow transformed into better or different methods or into scientific methods. Rather, these methods can be subject to ethnomethodological inquiry also. (Refer to studies of the work of scientists by Lynch, 1985.)

The result is that ethnomethodology produces a view of all activities within the world of everyday life, even those of social or other scientists, as first and foremost practical activities subject to ethnomethodological analysis. This view does not result in ethnomethodology's becoming a sociology of science or a sociology of sociology, however. Rather the methods of sociology and of all the sciences are revealed to be practical accomplishments in their own right.

So ethnomethodology represents the search to discover members' methods of accomplishing the complex tasks of everyday life, including methods of reasoning, methods of interpretation, methods of communicating, methods of interacting, methods of doing conversation, methods of doing whatever. This means that ethnomethodology is a perspective that has relevance for all the sciences, political science, economics, biology, and so on, because studies can be done of practical political, economic, or biological reasoning and of the actualities of their research practices.

And since many of these practices are repeated and patterned, their methodical character, their orderliness, i.e., their organization, can be discovered.

Ethnomethodology is oriented to the discovery and analysis of such orderliness. It is not interested in explanation or the analysis of originary or causal relations.

Indexicality and Reflexivity

Two of the major concepts of ethnomethodology are indexicality and reflexivity. Indexicality refers to the fact that, for members, the meaning of what they say and do is dependent on the context in which their doing and saying occurs. Members are able to understand an action or utterance because they also know something about the time and place of occurrence, who the parties were, what had occurred previously, the relationship between the parties, what occurred next, and so forth.

Members are interested in the particularities of actions and utterances and not in standardized or idealized meanings. In achieving understanding, members take notice of and utilize all that is available to them in the context. Such details Garfinkel has called indexical particulars. Indexicality is thus part and parcel of every ordinary situation of action and talk and cannot be remedied by developing standardized or idealized concepts or terms. Members do and must use indexical particulars in making sense of their circumstances; it is an essential property of the way they make interpretations and arrive at sense, decision, action, etc.

Reflexivity refers to the fact that, for members, "the features of the real society are produced by persons' motivated compliance with these background expectancies" (Garfinkel, 1967); that is, commonsense knowledge provides members with knowledge of the features of society, and these same features are then complied with. There is thus a reflexive relation between the 'facts' about society and the ways that members use practical reasoning and commonsense knowledge to depict society. Accounts are reflexively tied to those matters and circumstances that are being accounted for.

Garfinkel (1967) stated this as follows: "members' accounts are reflexively and essentially tied for their rational features to the socially organized occasion of their use, for they are *features* of the socially organized occasions of their use" (p. 4).

Accounts reveal features of the setting, as Leiter (1980) put it,

> which, in turn, depend on the setting for their specific sense. The features of a setting that are revealed by descriptive accounts and behavior do not just explicate the setting; they, in turn, are explicated by the setting.... [B]ecause accounts consist of indexical expressions they depend on the setting for their meaning. At the same time, a feature of any setting is the production of accounts. The setting gives meaning to talk and behavior within it, while at the same time, it exists in and through that very talk and behavior. (p. 139)

The Ethnomethodological Attitude

The natural attitude, as Husserl and Schutz showed, is the attitude of the person living in the world of everyday life. In that attitude persons accept things as they are, as they appear to be, without question. Social reality is regarded as simply there, as a world existing independent of perception. For persons who operate within the natural attitude, these 'facts' are accepted and are not subjected to further study. That is, how members have achieved this sense or interpretation of what the world is, how members actually experience and describe the social world as 'factual,' how members achieve, for themselves and for others, this sense of the massive, external, 'objective' quality of the social world, is not studied.

But it is precisely this that ethnomethodology wishes to study. Therefore, these methods for achieving a 'sense of the social world' as 'factual,' as 'out there,' as external, must be studied directly.

The ethnomethodologist does not say that the social world is this way or that but instead brackets, or sets aside, all such ideas and beliefs and does not consider them true or false. Instead the focus is on how persons make the social world factual, observable, and real for themselves. This would include, of course, how they talk about it.

So, rather than taking a position that one version of the world or the other is correct, the ethnomethodologist would ask instead how members go about deciding matters of correctness (or truth), what interpretations they engage in, how they talk about such matters, and how they achieve what they would recognize as and call correct.

Society is not denied, nor does it disappear, as some critics have claimed. For members, society is always there, but for the ethnomethodologist, that which members consider to be society is capable of study only in and through members' practices. These practices include their completed (past) activities as well as their present, still on-going activities, including speaking and acting. Past activities are available for study through recall, written materials, and in whatever ways these are referred to and oriented to by members.

Ethnomethodology Is Not Ethnography

Ethnomethodology represents a 'methodography,' i.e., a search for the practices or methods by which the "substantive features of the setting are made observable" (Zimmerman and Pollner, 1970). It is therefore not the same as ethnography.

Rather than focusing on what members do, in terms of such substantive headings as, for example, marriage, divorce, kinship, and property in family sociology (which are concerns of conventional ethnography), an ethnomethodological approach would focus on members' methods for making visible, demonstrable, and accountable the particular settings' features, e.g., how members recognize, describe, and make accountable, for themselves, such matters as 'family,' 'marriage,' 'kinship,' etc. The result would be discoveries with regard to a set of members' practices for accounting for such matters, i.e., what and how categorization devices are used, how persons are 'counted' ('traced,' 'located') or not counted; how persons are 'classified' and 'unclassified,' 'collected' and 'separated' for particular purposes, and in what ways matters such as these are 'decided and done' on various types of occasions and for various purposes.

Ethnomethodological studies may discover categorization practices that underlie family or kinship terminological assignments and, as a collection of practices, members' categorization practices (or, as Sacks, 1992, called them, membership categorization devices, or MCDs), may be found to display general (or invariant) features or structures that hold across particular occasions, particular speakers, etc.

The discovery and analysis of methods of categorization may lead more deeply into kinship terminologies or away from kinship to everyday practices in other areas, e.g., racial, class, personality, or pronoun references. The phenomenon of 'members' methods of categorization,' as a members' method, is not limited by virtue of any prior preconceptions to such conventional topics as kinship. In fact, ethnomethodology is indifferent to all alternative theorizings and conceptualizings.

Ethnomethodological studies may be said to be, in part, critical of conventional work in the social sciences. The criticism is this: that conventional studies do not seek to study the phenomenon as a members' phenomenon and as an ongoing socially produced phenomenon, in all its details, following it wherever it may lead but instead, try to specify in advance, even before the research has begun, what the topic is exactly, how the topic is to be studied, and what form the results of the inquiry should take; for example, that variables must be defined, that measurement is necessary, that statistical or quantitative analysis is essential, that empirical generalizations must be proposed, that interpretation of findings in relation to prevailing general theories (as found in the sociological literature) is necessary, and that, preferably, a causal theory is to be developed.

It is not difficult to understand why social scientists who accept such a model of what research should look like are skeptical and critical of ethnomethodological studies, which do not appear in this form at all.

As another example, ethnographers may be interested in such matters as beliefs and the content of beliefs, i.e., what beliefs are about. The ethnographer may then describe what persons believe, what they tell each other to believe, to whom they tell certain beliefs, and how they separate their beliefs into such groupings as religion, tradition, economics, or politics. The emphasis in such research is on systematically collecting and studying such beliefs.

In contrast, instead of being concerned primarily with the contents of beliefs, the ethnomethodologist would consider beliefs as members' ways of accounting to themselves for certain matters.

Beliefs, and their expression, would be studied to see how they are used and what work they actually do for members, i.e., what they accomplish. One discovery may be that 'beliefs' serve to explain action; for example, it may be said that a person watered crops because that person believed that water helped crops grow. Such words as 'believe' may be used by

members to interpret, or make sense of, peoples' actions (Coulter, 1979b). If such words and ideas as 'belief' or 'motive' are used by them, then how these are used and what their use accomplishes would be subjected to study.

Such studies would reveal what commonsense knowledge and understandings in their everyday meanings (uses) are for members by making commonsense knowledge and understandings the topic of study.

Further, ethnographic and conventional social science approaches generally try to describe the everyday practices of members of society by using conceptual constructions to make events observable and understandable, i.e., by 'constructing' everyday reality. That is, formal analytic constructs used by the social sciences would be considered by ethnomethodology to be a set of accounts that hide or make unavailable the concrete, specific particulars that are involved in members' practices. Ethnomethodology claims to be indifferent to such analytic accounts and instead provides an asymmetrically alternate form of social analysis by focusing on the achievement of every form of social order as practical action (Garfinkel and Wieder, 1992).

Later Work

In his later work, Garfinkel (1986, 2002) and his colleagues developed what is referred to as the 'studies of work' program, in which a more radical ethnomethodology seeks to respecify the phenomena of order as 'achieved phenomena of order,' whose organization and methods of achievement are to be discovered through direct, lived experience, examined, and described in and as of particular concrete situations. The 'haecceities,' or the 'just thisness,' of orderly phenomena require a focus on particularities and even efforts to achieve competence in the production of the phenomena under study. Thus, one version of 'unique adequacy' for the study of such phenomena requires a 'vulgar competence' by the ethnomethodologist, as for example demonstrated in Sudnow's study (1978) of the accomplishment of improvisational jazz at the piano, wherein he studied his own performance and described the phenomena of order he discovered. The methods used in the research are already possessed by the competent performer who knows and is competent in their use since he can produce a competent performance. This also includes competence in recognizing, identifying, and displaying the orderly phenomenon, i.e., playing improvisational jazz. Similarly, Livingston (1986), by learning how to do a mathematician's work, was able not only to display his competence to perform mathematical proofs but also to identify, recognize, and describe the methods by which such proofs were accomplished.

In another sense of unique adequacy, the phenomena of order can be said to "already possess whatever as methods methods could be of [finding them]" (Garfinkel and Wieder, 1992: 182). That is, the methods for observing, examining, counting, collecting, and describing the phenomena are already contained or incorporated within the phenomena as a lived local production. The methods for studying the phenomena of order are those that are uniquely suited to it, and no prescribed research methodologies are to be selected in advance. Whether the findings from such studies can or ought to be generalized or offered as revealing general rather than particularistic discoveries is a point of argument because some critics (Wilson, 2003; Lynch, 1993) contend that such studies result in ethnomethodology's becoming "an 'experiential practice,' the purpose of which is to encounter directly and unmediatedly the lived ordinariness of concrete situations" (Wilson, 2003).

As ethnomethodology continues to develop and is taken up by researchers in various fields, including anthropology, communication studies, education, sociology, information technology, interaction analysis, social studies of science, and so on, it provides a "multi-faceted focus on the local social orders" that are enacted in various situations, particularly "embodied, endogenous, witnessed practices" (Rawls in Garfinkel, 2002) and thereby a rich alternative perspective in the social sciences.

Ethnomethodology is, therefore, a genuine, reflexive social science. As such, it offers to contribute to all studies of the world of everyday life, including studies of the work of the sciences themselves.

Ethnoscience

E Hunn, University of Washington, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

The term 'ethnoscience' may be read at least two ways. First, by analogy with such more specific terms as ethnobotany, ethno-ecology, ethno-astronomy, ethnomedicine, and ethnogeography, ethnoscience may refer to the sciences of other societies and cultures, that is, the bodies of empirically grounded knowledge of one or another aspect of the natural world as compiled by those who participate in cultural traditions more or less independent of our own. Thus, for example, "Navaho Indian ethnoentomology" (Wyman and Bailey, 1964) includes a detailed account of Navajo knowledge of insects; Tzeltal ethnobotany (Berlin *et al.*, 1974) is an encyclopedic compilation of a Tzeltal Mayan community's names for and understandings of the plants in their vicinity, within a universalist comparative

theoretical framework. Conklin (1980) provides an exhaustive bibliography of such studies through 1971.

Given the historical grounding of anthropological fieldwork at some remove from modern urban, 'Western' societies, ethnoscientific studies have largely focused on peasant, tribal, or band societies more or less tenuously linked to global markets. Older authors might have characterized their work as the study of 'primitive medicine' or 'plant use by primitive peoples' (Castetter, 1944). Nevertheless, to speak of ethnoscience implies a radical notion, to wit, that **science** is not just a product of Renaissance genius and modernist dedication, but rather an impulse common to all humanity. In this sense, ethnoscience mandates a comparative analysis of the various historic forms of scientific investigation.

Ethnoscientific studies are of particular interest for linguists in that each such science is grounded in a technical vocabulary. Comparative ethnosemantic analyses of these vocabularies may define both cognitive universals and the range of conceptual realities possible within each domain. Beyond this semantic base ethnoscientific studies may address questions of worldview, cultural and ecological adaptation, and prehistory beyond the scope of this article.

For example, Mayan astronomy employed but a small vocabulary for celestial features but developed a system of precise calculations capable of predicting lunar and solar eclipses and planetary movements, these interpreted as cosmic guides to human fate (Aveni, 2001). Ethnomedicine involves the causal association of several hundred plant names and an ethno-anatomical nomenclature with perhaps a hundred terms for disease symptoms and syndromes. These associations motivate hundreds of specific treatment recipes, many of which can be shown to be effective within the conceptual frame of a specific culture (Ortiz de Montellano, 1990). Ethnogeographies involve toponymic inventories of approximately 500 terms for each face-to-face community (Hunn, 1994). These may be analyzed in terms of their descriptive semantics, their spatial and ecological patterning, and their moral power (Basso, 1996; Hunn, 1996).

Ethnobiology integrates a diversity of disciplines, not all clearly relevant to the study of language, yet, as with modern systematic biology, all ethnobiological knowledge systems studied to date involve an extensive and systematic nomenclature and classification of living entities. Every language names several hundred basic categories of plants and a similar number of animals and recognizes patterns of similarity or 'kinship' among them that we may represent as a taxonomic hierarchy (see Figure 1), closely comparable to the Linnaean taxonomy we now interpret as representing evolutionary history (Berlin, 1992).

The term 'ethnoscience' has also been used to refer to a particular school of ethnographic theory and practice which achieved a certain prominence, particularly in the United States, during the 1960s. Sturtevant (1964) took stock of this emerging theoretical challenge. As he noted, ethnoscience might be understood as in our prior characterization, but might also refer to a methodological program to develop scientific ethnography, that is, ethnography less dependent on subjective impressions, less subject to the biases of the ethnographer, and one which by

Figure 1 Ethnobiological taxonomic structure, after Berlin (1992). (* indicates an 'unaffiliated generic').

means of systematic elicitation procedures, modeled on those then favored by structural linguists, might produce replicable cultural descriptions. Ethnoscience as ethnographic critique was indebted in many ways to linguistic theory: to structural linguistics for the emphasis on 'scientific' discovery procedures (Frake, 1962; Metzger and Williams, 1966), but also to the newly prominent Chomskyan perspective, in which grammars are sets of abstract cognitive 'rules' for generating appropriate (i.e., grammatical) sentences or, more generally, 'rules' that generate appropriate behavior within specifiable social and cultural contexts (Goodenough, 1957).

Ethnoscience in this latter sense died with the 1960s (Murray, 1998), but lives on in contemporary cognitive anthropology and in ethnoscientific studies in the first sense noted. Both subscribe to the notion that a basic goal of ethnography is to faithfully translate from the vernacular local understandings of the natural and social worlds, and to seek to appreciate how these understandings reflect our common humanity.

Etymology

P Durkin, Oxford English Dictionary, Oxon, UK

© 2006 Elsevier Ltd. All rights reserved.

The Historical Background: Pre-modern Etymology

The etymology of the word *etymology* (ultimately from Greek *etumon* 'true meaning or form', in turn from *etumos* 'true') is a perfect illustration of the 'etymological fallacy', the view that the earliest meaning of a word is truer or more correct than subsequent meanings. This approach, running counter to the modern stress on the arbitrariness of the linguistic sign, vitiates much pre-modern etymological work, as does the lack of any systematic methodology, lending some truth to the famous remark attributed to Voltaire that "in etymology, consonants signify little and vowels nothing at all" (and variants thereof). Nonetheless, the insights, intuitions, and traditions of earlier commentators can sometimes provide useful stimuli for etymological research. For instance, where a Latin or Greek word is of unknown etymology, it can be useful to know that it was regarded as a loanword in antiquity, even if no likely etymon is identifiable. Furthermore, the intuitions of contemporaries can have interesting analogies with the

means of systematic elicitation procedures, modeled on those then favored by structural linguists, might produce replicable cultural descriptions. Ethnoscience as ethnographic critique was indebted in many ways to linguistic theory: to structural linguistics for the emphasis on 'scientific' discovery procedures (Frake, 1962; Metzger and Williams, 1966), but also to the newly prominent Chomskyan perspective, in which grammars are sets of abstract cognitive 'rules' for generating appropriate (i.e., grammatical) sentences or, more generally, 'rules' that generate appropriate behavior within specifiable social and cultural contexts (Goodenough, 1957).

Ethnoscience in this latter sense died with the 1960s (Murray, 1998), but lives on in contemporary cognitive anthropology and in ethnoscientific studies in the first sense noted. Both subscribe to the notion that a basic goal of ethnography is to faithfully translate from the vernacular local understandings of the natural and social worlds, and to seek to appreciate how these understandings reflect our common humanity.

The Historical Background: Pre-modern Etymology

The etymology of the word *etymology* (ultimately from Greek *etumon* 'true meaning or form', in turn from *etumos* 'true') is a perfect illustration of the 'etymological fallacy', the view that the earliest meaning of a word is truer or more correct than subsequent meanings. This approach, running counter to the modern stress on the arbitrariness of the linguistic sign, vitiates much pre-modern etymological work, as does the lack of any systematic methodology, lending some truth to the famous remark attributed to Voltaire that "in etymology, consonants signify little and vowels nothing at all" (and variants thereof). Nonetheless, the insights, intuitions, and traditions of earlier commentators can sometimes provide useful stimuli for etymological research. For instance, where a Latin or Greek word is of unknown etymology, it can be useful to know that it was regarded as a loanword in antiquity, even if no likely etymon is identifiable. Furthermore, the intuitions of contemporaries can have interesting analogies with the

process of historical change known as folk etymology, and hence can suggest explanations for formal and semantic change (*see* **Folk Etymology; Historiography of Linguistics**).

The Place of Etymology in Modern Linguistics

Modern etymological work is an essential component of, and is in an inextricable symbiotic relationship with, the comparative method and the great 19th-century advances in the methodology of historical linguistics.

In the broadest use of the term, etymology is in fact little more than a variety of 'applied historical linguistics', and its methodology is the same as that of historical linguistics more broadly. What this article will not attempt to do is to give an over-brief summary of this basic methodology, which is dealt with in full elsewhere in the encyclopedia (*see* **Historical and Comparative Linguistics in the 19th Century**). Instead, what follows is a survey of the different areas of linguistics where etymology plays a role, and of how different contexts influence methodology. In particular, I will look at the tradition of etymology in lexicography, and at related stand-alone studies of single lexical items in the scholarly literature.

Looking more closely at the term *etymology* itself, several distinct, albeit overlapping, uses of the word are identifiable in modern scholarship:

1. The methodology by which the history and/or prehistory of the lexis of a language may be traced, and/or its affiliations in other languages. (Thus conceived, etymology comprises all applications of the methodology of historical and comparative linguistics as manifested at the level of the lexeme, and it cannot usefully be separated from a general account of the methodology of the discipline.)
2. An account of the history of a word, including all major developments in meaning and form, so far as these can be traced in historical documents or reconstructed from the available evidence, together with an account where appropriate of the word's affiliations in other languages, or, in the case of a loanword, a similar account of the relevant facts in the word's history within the donor language(s), and sometimes also the ulterior history of the word within the donor language or beyond. This will often be abbreviated, by restriction to a particular historical period, or by selective presentation of the most significant data. Where there is doubt or uncertainty, rival explanations will normally be summarized and appraised (although this will seldom constitute a full summary of earlier suggestions). This is what is normally represented by an entry in an etymological dictionary, or by the etymological component of a general dictionary (in an historical dictionary, various components of the dictionary entry when taken together will provide this information). There is also a corresponding non-countable use to denote the researching and provision of this sort of information.
3. More narrowly defined, any of various subcomponents. In the case of a word that is taken to form part of the inherited wordstock of a language, this may be a listing of the word's immediate or remoter cognates (the similarly descended forms in related languages), with or without a reconstructed proto-form. In the case of a loanword, this may amount to no more than the immediate donor form, or even just an indication of the language from which it is borrowed.
4. Any of the competing explanations of a word's origin or development (e.g., an article in a journal might have the title 'A new etymology of English *boy*'). Sometimes more specifically, a suggestion that a word may originate in a particular language or group of languages (e.g., "In place of the Germanic etymology traditionally posited for this word, some scholars have instead suggested a Celtic etymology.").

The second of these definitions will be most central in the remainder of this article, although it is as well to bear in mind that all of these uses of the word are current, and that the dividing lines between them are not always clear-cut in practice.

Etymology and Historical and Comparative Grammars

Comparative etymologies (i.e., the establishment of cognates and proto-forms) and comparative grammars are in a completely symbiotic, and even somewhat circular, relationship: the correspondences established between the sounds and forms in two or more languages depend fundamentally on a group of firmly established etymologies (ideally with cognates in all of the languages concerned), and conversely the individual etymologies are given their strength by the regular correspondences identified in the comparative grammar. Nonetheless, it is worth bearing in mind that these sorts of secure etymologies are normally not numerous. This is not necessarily a problem for the historical grammar, but the etymologist should be wary that these few secure etymologies do not exercise a "gravitational pull" that attracts other, weaker etymologies. However good a formal "fit" is found,

and however many other words show the same formal correspondence, an etymology that is supported by only a single probable cognate with a poor semantic correspondence remains weak. Perhaps the best illustration of this is provided by browsing through the Indo-European etymologies in Pokorny (1959–1969) (or if one does not have a reading knowledge of German, the etymologies in Mallory and Adams (1997) and the further literature cited there): the reader can easily work through, separating those etymologies with ample support from those where only a small number of forms in widely separated languages are adduced, or separating those where both the formal and the semantic correspondence are exact from those where formal difficulties are flagged or where the semantic correspondence is tenuous.

Cognates can be established wherever a relationship between two languages is established (the two go hand in hand), and such etymologies will therefore be found for a great many of the world's languages, and not just in the familiar territory of Indo-European etymology. However, when they are not supported by a good deal of historical documentation for the languages concerned, it is likely that the semantic component in such etymologies will be minimal, and all that can be constructed are proto-forms for certain shared lexemes of common descent, with a semantic label attached which is little more than the aggregate of the modern meanings of the words. This is also the area of etymological work where theories of areal diffusion may sometimes present serious challenges to more traditional analyses of common descent (*see* **Areal Linguistics**). In some languages (for instance, Tahitian or Tuamotuan among Polynesian languages), extensive replacement of lexis as a result of taboo may make even this sort of etymological work difficult, and it is of course impossible for languages that are true isolates (e.g., Basque).

The rest of this article will be concerned chiefly with languages where there is more historical data and where more detailed etymologies can therefore be prepared. Such etymologies are of vital importance to historical (as opposed to comparative) grammar, as it is essential that form and meaning can be traced through the history of a language if detailed conclusions are to be drawn about the internal development of sounds and morphology. They also provide an essential point of reference for work in areas where information is more limited.

Etymology and Dictionaries

Just as a symbiotic relationship exists between etymology and comparative grammars, so it does also between etymology and dictionaries. To take each of the major types in turn:

General Dictionaries

In some smaller dictionaries, particularly the desktop synchronic ready-reference dictionary, the etymological section of each entry is in a sense detachable: whatever the other arguments for or against its inclusion, little emendation would be needed to make the remainder of the dictionary comprehensible were it removed. Conversely, the etymologies would still make reasonable sense if divorced from the rest of the dictionary, so long as some brief identifier of the core meaning of each word were retained to tell apart homographs.

Historical Dictionaries

The same is not true of an historical dictionary, where the detailed account of historical forms and meanings has innumerable points of intersection with the etymology section proper (normally contained within square brackets, or otherwise marked off from the rest of the text). The etymology (in the sense of #2 above) is one of the main principles determining the division of the material into separate entries: all of the material which is developed from a single origin and which has the same form in the modern language will be kept together in a single entry. Taking the *Oxford English Dictionary* as the typical example of such a dictionary, homonyms such as *mean* 'common' (of Germanic origin) and *mean* 'average' (of Romance origin) are divided on the basis of their distinct origins, even though the subsequent semantic development brings some senses of each word so close together that it becomes almost arbitrary to assign them to one entry or the other. Affixes will often be included in the dictionary's headword list, for convenience as much as anything in the presentation of etymologies within the work, even though this means that what is strictly a part of the grammar of the language is presented for pragmatic reasons as a part of the lexis.

Etymological Dictionaries

Some varieties of comprehensive etymological dictionary differ from the historical dictionary only in that the focus is more restrictively on those facts which are most important in understanding the historical development of the word. Comprehensive illustration of continuing use in a given sense will not normally be found: see for example Corominas (1980–1991), which gives detailed etymological discussion and supporting documentation on early use, but does not illustrate subsequent use except where this is

necessary for the discussion of major developments in form or meaning.

The *Französisches Etymologisches Wörterbuch*, perhaps the greatest example of an etymological dictionary of a modern language, differs also in that the organizational principle is the etymon (e.g., a Latin word which has reflexes in French, or a reconstructed Frankish form borrowed into Old French) and not the modern word forms. A base word and its derivatives will be found under a single headword, as will etymological doublets which differ greatly in modern form. So, under Latin *mĭttĕre* one finds *message* and *messager* alongside *mettre*, *mise*, *entremettre*, *démettre*, *émettre*, etc., while under Latin *ŏpĕrari* one finds *ouvrer* alongside *opération*, *opérateur*, *opérer*, etc. It is also notable for its comprehensive listing of regional forms (on the structure of *FEW,* see Büchi (1996)).

Single-volume etymological dictionaries of a major language are sometimes modeled directly on a larger parent work, such as the *Oxford Dictionary of English Etymology,* which is based on the materials of the *OED* although supplementing it in some respects. Sometimes they stand alone, such as the venerable Kluge (2002) or the younger Pfeifer (1992), both of which draw on the tradition of historical dictionaries of German in adducing early forms and meanings, but in both of which the internal history may often seem underplayed somewhat in comparison with the etymological discussions in *FEW* or *OED*.

A particularly clear model for the structure of an etymological dictionary (well characterized by its subtitle *histoire des mots*) is presented by Ernout-Meillet (1932), where the history of each word and its derivatives within Latin are presented in a succinct summary, followed by the etymology, in which succinctness is again the key in both the presentation of cognates and the selective discussion of rival hypotheses.

The Article and Monograph Literature

Separate monograph- or article-length studies of the etymology of individual words or of groups of words (e.g., Schuchardt (1903–1904) or Ross (1952)) belong in the same tradition as the etymological or historical dictionary, and the two are fundamentally interdependent. Without parallels (preferably close in date and cultural context), any discrepancy in the semantic or formal data will give cause for concern, no matter how ingenious an *ad hoc* explanation is hit upon to explain it. The etymologies proposed for a particular language therefore form a closely related set, whether they are presented together in a dictionary or separately in individual studies.

Major Categories of Etymology

It can be useful to classify etymologies in three broad groupings.

Internal Formations

An interesting group is formed by onomatopoeic and other expressive formations (including formations showing phonesthemes whose gradual convergence and productivity can often be traced, for instance, English *flip*, *flop*, *flounder* all developing as additions to the existing group shown by *fling*, *flounce*, etc. (*see*), along with practically arbitrary neologisms (for example modern proprietary names such as *Kodak*). However, far more numerous in most languages are formations showing various derivational processes such as compounding, affixation, or conversion (*see* **Word Formation**). Here the role of the etymologist is normally quite simple: one must ensure that the formation conforms to the established patterns of word formation in the language in question, and, also, for historically well-documented languages, that the respective dates of attestation of the proposed parent and child do not contradict the supposed etymology. Where difficulties do arise (for instance, where a noun-forming suffix apparently forms an adjective, or a compound occurs earlier than the corresponding simplex), one must ensure that there are not alternative, more likely explanations, and if there are not, the difficulty must be flagged for the historical grammar (in the case of unusual word formation) or for the history of the lexicon (where the dating of a particular lexical item is at issue). The study of internal formations is thus uncontroversially a part of the study of the internal history of the lexis of a language.

Loanwords

The available data is the factor determining what sort of etymology work can be attempted for a loanword. A classic illustration of this is provided by Ross (1952), where the word *ginger* is traced back from early modern documentation in European languages, through Arabic, to various languages of South Asia; at each stage in the etymology, the procedure is subtly different, reflecting the different nature and extent of the available historical data.

Similarly, the differing information available for donor language and recipient can often result in an asymmetry in etymologies: an obvious case is borrowing into European languages directly from more "exotic" languages as a result of contact through trade, exploration, or colonization. Taking as an example Tupi loans in Portuguese, one can trace back the earliest forms in Portuguese and look at their contexts and what these say about the likely date and

circumstances of the borrowing, but for the Tupi side of the equation this information is normally absent. For examples, see the excellent coverage in Cunha (1978). What one can do for both languages is to apply the basic methodology of checking whether: (a) the thing denoted is native to the region where the language is spoken; (b) the word shows semantic or morphological complexity; (c) it has an unusual phonological or morphological shape for either language; (d) there are related lexical items in the language. But without supporting historical data, there will be no certainty that changes have not been masked by accommodation to either language, folk etymological alteration, etc.

Sometimes, the overwhelming amount of historical data available can pose a problem, if it has not been covered adequately by historical lexicography. German was in the late 19th century a (if not the) predominant language of scientific research, but the coverage of scientific vocabulary in dictionaries of German is poor (for various, interesting, cultural-historical reasons), and the researcher wanting to explore the etymologies of scientific words in other European languages in that period is often only able to put together a partial impression of a word's history within German through tracking bibliographical leads through the technical literature (or in other words, by becoming temporarily an historian of science).

Ross (1952) is also a good example of the importance of external history, *realia*, and textual criticism (indeed of old-style philology) in this sort of work – which is perhaps one of the reasons for the limited appeal of etymology in comparison with 'purer' areas of linguistics.

Inherited Words

Reconstruction at great historical depth has already been touched on, but ideally this will dovetail with the historical data (where it is available). For example, modern English *mare* 'female horse' can be shown (on the basis of comparative reconstruction across the Germanic languages) to be the formal reflex of a Germanic word for 'male horse' but to have the sense of its corresponding feminine derivative. However, it is only through careful combing of the recorded attestations in Old and Middle English that the complicated process by which this came about can be traced.

Historically well-documented periods and the well-trodden ground of major world languages are in many ways ideal training grounds for any etymological research and provide an important test for the universality of explanations proposed for less well-documented areas (that whatever is hypothesized should have parallels in the recorded history of languages). However, it is also necessary to bear in mind the atypicality of historically documented languages with regard to the literary transmission of words, senses, and forms, the influence of written language on formal development, etc.

Names

In most traditions, proper names constitute a separate branch of etymological work, although a vital one. Here the semantic component is stripped bare, but paradoxically the tracing of historical forms is vital, because names (having reference but no denotation) are so prone to alteration. For a model example of this sort of work, see the publications of the English Place-Name Society, in which specialist documentation on individual place names is found side by side with lexicographical analysis examining the relationship between place name elements and the general lexis (*see* further **Place Names**; **Personal Names**; **Nicknames**).

Issues of Words, Word Forms, Polysemy, and Dictionary Entries

The problem of what constitutes a lexical 'word' has many implications for etymological work. Various processes can have radical implications for the coherence of a lexical item, such as:

- multiple inputs, e.g., where a word shows a blend of two input words, or where it has been borrowed from one language in part via another
- reborrowing, e.g., where a word is borrowed first in one sense, only to show subsequent semantic influence from the donor language over a period amounting perhaps to several centuries
- mergers and splits (or more commonly gradual divergences)
- polysemy
- variation in form

This is often explicit in dictionaries (especially historical dictionaries where the historical data is presented up front), but it is potentially more dangerous when etymologies are discussed or adduced in other contexts. In many cases, there will be doubt whether one is dealing with one or more lexical items, and consequently whether a single etymology can apply. What appears to be a seamless history in terms of formal and semantic coherence may start to fall apart if one looks more closely at the individual examples of early use, and it may be that a number of slightly different etymologies have come together in a single lexical item. (For an interesting experiment in this area, at least with regard to diversity of form, see Roger Lass's

work on the *Linguistic Atlas of Early Middle English* (Lass), where a separate etymology will be provided for each form-type in a database.)

Issues of Semantics

Semantic transfers in historically documented periods often focus on particular attributes to the neglect of others. To take a notorious example, the British bird name *robin* has in North America been transferred to a much larger bird which does, however, also have a distinctive red breast, while in Australia and New Zealand it denotes any of various small flycatchers with brightly colored breasts. Similarly, the British bird name *magpie* has in Australia been transferred to a bird which is also black and white, but, while the European bird has a raucous cry, the Australian bird is famous for its beautiful song, so much so that the soprano Joan Sutherland has been referred to as an 'Australian magpie.'

An artifact or piece of technology and its name are not necessarily borrowed together (for instance, Basque *golde* 'plough' is a borrowing from Latin *culter*, but the artifact was probably in use among Basque speakers long before the word was borrowed from Latin). Similarly, core vocabulary items are frequently borrowed in language contact situations. English has borrowed from French or from Scandinavian languages such basic words as *face* or the pronoun *they*, or (all from the Swedesh list of basic vocabulary items) *person*, *mountain*, *skin*, *grease*, *egg* (albeit in the last instance displacing a native cognate word). The words for 'head' in modern French and German show striking parallels: in both languages the inherited Indo-European word shows metaphorization (German *haupt* 'main, chief', French *chef* 'leader, boss') and has been displaced in its core meaning by words which in turn show metaphorization of words for vessels (German *Kopf* 'head', originally 'bowl', French *tête* 'head', originally 'pot'). Avoidance of obscenity, blasphemy, or other culturally marked connotations can lead to alteration of form (e.g., English *heck* for *hell*), replacement by a near homophone (e.g., English *ruddy* for *bloody*), or substitution of a different lexical item (e.g., in Japanese substitution in many contexts of *yon* for *shi* 'four', a homophone of *shi* 'death').

Even more important, the mechanisms for semantic change have as yet not shown themselves to be reducible to system in the same way as phonological or morphological change. Such familiar processes as broadening, narrowing, pejoration, amelioration, hyperbole, litotes, metaphor, and metonymy are all too apt to sound like special pleading in support of a favored etymology, especially one that provides an enticingly exact formal 'fit'. The pages of etymological dictionaries are all too full of such comments as "but this suggestion seems unconvincing from a semantic point of view," bringing to prominence what can seem an uncomfortably subjective element in etymological work. In the absence of a deeper understanding of the processes of semantic change, the assessment of the intrinsic semantic plausibility of etymological suggestions remains difficult, and it is not surprising that opinions frequently differ.

Manuals and Textbooks

Some earlier manuals attempt to embrace all of the material covered by the first definition above, at least insofar as this touches on an individual language. Thus, at the end of the 19th century, Walter Skeat made various attempts at a comprehensive primer of English etymology, to provide all the necessary historical and comparative grammar to enable the budding scholar to trace English etymologies through Germanic and beyond to Indo-European, as well as to provide the most essential data on the internal and external history of the major donor languages such as Old Norse and French. Most later attempts are unsurprisingly much less adventurous, although there are exceptions such as (for English again) Bammesberger (1984) or Lockwood (1995), which attempt to give students the basic framework and a taste of what etymology has to offer, or Ross (1958), which attempts to give a basic introduction to methodology and an interesting guide to using some of the major etymological dictionaries. Crucially, all such manuals are conceived as supplements and adjuncts to the principal historical grammars, and can only be used as such. For guidance through the basic tools of the trade, the modern equivalent of the user envisaged by Skeat should turn to the many excellent introductions to historical linguistics and its various branches, of which etymology can properly be regarded as a type of 'applied' manifestation.

Another strand is represented by studies of the methodology and achievements of etymological work (as it were, the 'meta etymology manual'). Outstanding in this field is the work of Yakov Malkiel.

Languages of Etymological Scholarship

Etymological scholarship is increasingly often written either in English or in the language being studied, in common with most other areas of linguistics. However, as will have been evident from the rest of this article, much of the most important existing literature is in German or French. This is in part a result of the particular longevity of etymological scholarship, and

also of its propensity to cross the barriers of national schools of linguistic study.

Some Possibilities for Future Work in Etymology, Especially for the Individual Scholar

Undertaking new etymological research, especially when not a component of an attempt to establish or build on the comparative grammar of a group of languages, can seem an unattractive prospect, especially for the individual scholar. For many languages, the existing body of literature is large and extremely technical, embracing components of a number of different core areas of historical linguistics. Where a promising amount of historical data is available, it is probably already well worked over in dictionaries and in individual studies, and is liable to be worked over again periodically by specialist teams (for instance on a dictionary project) who will be able to take advantage of leads that emerge during the course of reviewing the available records without the pressure constantly to be making new 'discoveries'. However, if the work of an individual scholar is well targeted, it can often present fresh insights and discoveries that can greatly enrich understanding of the history of a particular language or group of languages, as well as having more general theoretical implications. Some particular possibilities present themselves:

- All etymological or historical dictionaries list large numbers of words as being "of unknown origin" or "of uncertain origin" (or various other formulas to the same effect). Approached unwarily, such items can be a form of etymological quicksand, causing the newcomer to expend enormous energy in doing little more than reinvestigating well-known blind alleys. However, with a suitably focused method, such items can prove fertile ground for future work. Notable in this respect have been attempts to focus on such items for possible evidence of layers of loanwords, which the external history of a language would give grounds for expecting but which have only been identified in small numbers. For instance, Theo Vennemann has highlighted the possibilities for research on the large numbers of English words that have no secure etymology, or of the similarly large numbers of words with no secure etymology beyond the Germanic languages; of course, it must be acknowledged that findings of this sort will often be tentative and controversial, as is so often the case with any more adventurous work in etymology. Taking a different approach with the same body of material, Anatoly Liberman is engaged on an ambitious project surveying and reviewing previous attempts at etymologizing just such difficult words (often extending his gaze to suggestions made long before the development of modern comparative methodology) to see whether a grain or two of truth can be found among the chaff of previous attempts in the form of a promising idea that can be worked up further in the light of modern methods.
- Alongside words of unknown or uncertain etymology, etymological dictionaries are full of cases where two words or groups of words show puzzling similarities of form and meaning that etymologists have been loath to attribute to coincidence, but where it has nonetheless proved impossible hitherto to establish a completely satisfactory explanation of an etymological relationship. Careful targeted examination of such cases, so long as it observes the methodology of historical and comparative linguistics, might well yield more satisfying solutions, and perhaps even some fresh insights into the historical or comparative grammar of the language in question, or into the mechanisms of semantic change.
- As noted above, the mechanisms of semantic change are not nearly so well investigated as those of phonological and morphological change. Careful work on semantic development in historically documented periods, and on the semantics of loanwords (both oral and literary) where historical documentation is available for both donor language and recipient, could yield valuable insights for periods for which such documentation is lacking, as well as having implications for general understanding of processes of semantic change. Several new areas of research in historical semantics (for instance work in cognitive semantics such as that by Eve Sweetser, or the still expanding field of grammaticalization) have clear implications for work on etymology in remote or poorly documented periods.

The transmission of the Levantine linear alphabet to Greece, Anatolia, and Italy is an event of great importance, if only because these words you are now reading could not have been written (or would have been written entirely differently) had it not been for that event. It is no wonder that it has been the subject of much study and controversy.

In the present state of our knowledge, we can say that the alphabet, in its Phoenician form, reached Greece first, no earlier and not much later than the 9th century B.C.E., and subsequently spread from Greece to Anatolia and Italy. This is not to say that there are no other theories, involving, among others, an Aramaic origin, or a transmission through Anatolia to Greece, or a much earlier date. We will nevertheless start our discussion with the transmission of the Phoenician alphabet to Greece, and then move on to the early alphabetical writing systems of Anatolia and Italy.

Greece

At the end of the Mycenaean age (ca. 1100 B.C.E.), literacy was lost in Crete and other parts of the Greek-speaking world. Only in Cyprus was a modified form of the Aegean syllabary maintained to write the Greek language, and it remained in local use until Hellenistic times (*see* **Aegean Scripts**). Elsewhere in the Aegean, there was a lapse in literacy (the so-called 'Dark Ages'), which only came to an end with the adoption and adaptation by the Greeks of the Phoenician variety of the Canaanite linear *abjad*. The exact place and date of transmission are not known exactly and will always remain subject to revision from new archaeological finds. Much of the evidence has been irretrievably lost, because most writing was done on perishable materials such as wood, bark, and leather, and only occasionally on the more durable stone, metal, or pottery.

The Phoenician origin of the Greek alphabet, however, is not in any serious doubt, and is supported by several lines of evidence:

The transmission of the Levantine linear alphabet to Greece, Anatolia, and Italy is an event of great importance, if only because these words you are now reading could not have been written (or would have been written entirely differently) had it not been for that event. It is no wonder that it has been the subject of much study and controversy.

In the present state of our knowledge, we can say that the alphabet, in its Phoenician form, reached Greece first, no earlier and not much later than the 9th century B.C.E., and subsequently spread from Greece to Anatolia and Italy. This is not to say that there are no other theories, involving, among others, an Aramaic origin, or a transmission through Anatolia to Greece, or a much earlier date. We will nevertheless start our discussion with the transmission of the Phoenician alphabet to Greece, and then move on to the early alphabetical writing systems of Anatolia and Italy.

Greece

At the end of the Mycenaean age (ca. 1100 B.C.E.), literacy was lost in Crete and other parts of the Greek-speaking world. Only in Cyprus was a modified form of the Aegean syllabary maintained to write the Greek language, and it remained in local use until Hellenistic times (*see* **Aegean Scripts**). Elsewhere in the Aegean, there was a lapse in literacy (the so-called 'Dark Ages'), which only came to an end with the adoption and adaptation by the Greeks of the Phoenician variety of the Canaanite linear *abjad*. The exact place and date of transmission are not known exactly and will always remain subject to revision from new archaeological finds. Much of the evidence has been irretrievably lost, because most writing was done on perishable materials such as wood, bark, and leather, and only occasionally on the more durable stone, metal, or pottery.

The Phoenician origin of the Greek alphabet, however, is not in any serious doubt, and is supported by several lines of evidence:

- the shapes of the letters;
- the names of the letters;
- the order of the letters;
- the direction of writing (originally right to left in single-line inscriptions);
- the Greek tradition of referring to the letters as *φοινική γράμματα* (p^{h}oinikéː grámmata) 'Phoenician letters', transmitted to the Greeks by a legendary Phoenician ruler Kadmos.

Without meaning to demerit the Greek tradition, we will focus on the linguistic and paleographic aspects of the question.

The Shapes of the Letters

The majority of the early Greek letter shapes are nearly identical to their Phoenician prototypes (𐤂 g, 𐤃 d, 𐤄 h, 𐤆 z, 𐤈 ṭ, 𐤊 k, 𐤍 n, 𐤎 s, 𐤏 ʕ, 𐤐 p, 𐤓 r), especially if we take the archaic Cretan forms into account (𐤁 b, 𐤇 h, 𐤌 m, 𐤒 q) (see Table 1). The remaining differences mostly involve simple rotations and reflections (𐤋 > 𐤀, 𐤉 > 𐤉, 𐤔 > 𐤌/𐤎, 𐤕 > 𐤕).

The most interesting deviations are those of Phoenician 𐤅𐤅/w/. This regularly gives Greek υ, ϝ/u/, but as a consonant (/w/), it appears as ϝ, ϝ in archaic Cretan, and later, influenced by neighboring 𐤇, as ϝ. This also brought about the loss of the horizontal sidebar of Phoenician 𐤉 /j/, which turned into Cretan ϊ, ι /i/. The differentiation of vowel ϝ (placed at the end of the alphabet) and consonant ϝ looks like a deliberate attempt to create a doublet, by rotating the 'cup' of 𐤅 by 45 degrees. The lack of an unambiguous Greek equivalent to Phoenician 𐤑 /ṣ/ is also worth noting.

Three shapes are important for dating the transmission of the Phoenician alphabet to Greece. A *terminus post quem* is provided by Greek κ and μ, which come from the Phoenician 𐤊 and 𐤌, forms that only appear ca. 850 B.C.E., replacing earlier 𐤊 and 𐤌. Similarly, a *terminus ante quem* is provided by Greek Δ, which comes from Phoenician 𐤃, which after around 850 B.C.E. acquired a tail (𐤃). This would fix the time of transmission at approximately 850 B.C.E., even though the first actual evidence for the Greek alphabet is from about a century later.

The Names and Sound Values of the Letters

While the letter shapes do not exclude a non-Phoenician Northwest Semitic origin (the Aramaic and Hebrew alphabets were borrowed from the Phoenician one, and the shapes did not start to diverge until some time later), the names of the letters may provide us with some clues. Even though the Phoenician names of the letters have not been preserved, it seems clear that Hebrew and Aramaic borrowed some of the letter names from Phoenician (e.g., yôd instead of yād or yad 'hand' and mēm instead of mayim, maym 'water'), while other names were nativized (e.g., zayin, zayn 'weapon' and rēš 'head'). The Greek letter names, however, are all consistent with the likely Phoenician forms, including ξεῖ /kseː/ from *šeːn 'tooth,' and ῥῶ/r^{h}ôː/, from *rɔːš 'head.' Ζῆτα /dzêta/ looks as if derived from a Phoenician *dzɛːt 'olive,' but perhaps it simply derives from *dzɛːn 'weapon' > *ζῆ, and further > ζῆτα under the influence of neighboring ἦτα /hêta/ and θῆτα /t^{h}êta/.

Another argument for a very early or Aramaic origin of the Greek letter names is the final *-a* which appears on most letters. If the names had been borrowed very early, this *-a* might reflect the Proto-Semitic case ending *-a* (originally accusative, but marking the absolute state in North West Semitic). This, however, is inconsistent with the Greek name ἰῶτα /iôːta/, which clearly comes from Phoenician *yɔːd "hand," not from Proto-North-West Semitic *yada. Another theory is that Greek *-a* comes from the Aramaic emphatic definite article *-aː(ʔ)*. Again this is contradicted by ἰῶτα, and by the fact that the emphatic article is not added to letter names in Aramaic itself. A simple explanation is available in Greek itself, which did not allow final stops (*bɛːt, *ṭɛːt, (*dzɛːt), *yɔːd, *qɔːp) or consonant clusters (*ʔalp, *gaml, *dalt, *kapp, *labd, *samk).

Finally, it has also been suggested that the Greek treatment of the s(h)ibilant letters points to an Aramaic rather than a Phoenician transmission source. This is based on the fact that letter 𐤎 is sounded as an affricate /ks/ in Greek, while 𐤔 is sounded /s/, which is reminiscent of the Proto-Semitic values (respectively, the affricate /ts/ for 𐤎 and the sibilant /s/ for 𐤔). However, as can be seen in **Table 2**, there is no North-West Semitic dialect that preserved both those sound values.

On the subject of s(h)ibilants, even if Phoenician had reduced the Proto-Semitic s(h)ibilant inventory from nine to four, Greek only had use for two or three of them: plain /s/, the voiced affricate /dz/ (later metathesized into /zd/), and, in some dialects, also a voiceless affricate /ts/ or /tʃ/ (in most dialects reduced to /s/, /t/, /ss/ or /tt/). In particular, Greek had no phoneme /ʃ/, the most common s(h)ibilant in Phoenician. The Phoenician letter **name** *šeːn was adopted as Greek *ξει* /kseː/, with the foreign phoneme /ʃ/ apparently replaced by Greek /ks/. The **shape** of the letter (rotated to 𐤌 or 𐤎), however, was used to render Greek plain /s/.

Phoenician /s/, written 𐤎, gave Greek Ξ, but the name (*samk > *γ* /síŋma/ or *ν* /sán/) was transferred to the letter denoting plain /s/. Phoenician /dz/ 𐤆 gave

Greek I, also pronounced /dz/ at the time (later /zd/), while Phoenician ϟ /ts'/ was lost in the transition. The adopting Greek dialect apparently did not have a need for a voiceless affricate.

Besides the s(h)ibilants, there were other changes between Phoenician and Greek in the assignment of sound values to the letter shapes. The most important change is the creation of the Greek vowel letters.

The Greeks correctly assumed that the Phoenician letters were acrophonic: the first sound of the name provided the sound value of the letter. In the case of the very first Phoenician letter, called *ʔalp 'ox,' this led the Greeks, who lacked a phoneme /ʔ/, to assume that the sound value of the letter was /a/. Greek also did not have a phoneme /j/ ([j] was merely an allophone of /i/), so the letter *yɔ:d 'hand' was taken as acrophonic for /i/. The vowel /u/ was provided by Phoenician *waw 'hook' (although a doublet letter had to be created for the Greek phoneme /w/). Of the two Phoenician h-like sounds, Greek chose the more marked one (*ħ ɛ:t) to stand for the Greek rough breathing, which made Phoenician *he: 'hey!' (= Greek ἦ /ɛ́:/ 'hey!') available for the vowel /e/. For the final vowel, /o/, no obvious Phoenician model was available, and the Greeks adopted the remaining letter that to them sounded as if it was vowel-initial, ʕɛ:n 'eye,' perhaps by default, perhaps because the Greek word for 'eye' (ὀφθαλμός /op^{h}t^{h}almós/) starts with an o-.

Semitic has a category of **emphatic** consonants, pronounced glottalized in early Semitic, later in some languages velarized or pharyngealized. Of the original Proto-Afroasiatic/Proto-Semitic inventory,

/t'/, /ts'/, and /q/ (< /k'/) had survived into Phoenician. Greek had no emphatic consonants, but it had another marked category, that of aspirated stops (/p^h/, /t^h/, and /k^h/). Although aspiration is a (secondary) feature of the **non**emphatic consonants in Semitic, the Greeks did adopt Semitic *tɛːt to stand for Greek /t^h/, one marked consonant for another. The same was not done in the case of /q/, perhaps because in Semitic it no longer rated as a marked, emphatic consonant, perhaps because Greek at the time had not yet completely lost its labio-velar consonants k^w, g^w, and k^{hw} (still present in the Mycenean texts), and the back velar /q/ was first adopted to stand for /k^w/ where it remained (usually before /u/, as in *k^wek^wlos > ϙύκλος /kúklos/ 'circle'). This then led to the practice of using ϙόππα for back allophones of /k/ in general (i.e., before the vowels /u/ and /o/).

With the creation of vowel signs, and the reassignment of the s(h)ibilants and emphatics, most Greek sounds could now be rendered using the 'Phoenician letters.' Only the aspirates /p^h/, /k^h/, and, in some dialects, the voiceless affricate /ts/, still needed to be assigned a letter value. Furthermore, no distinction was yet made between short and long vowel phonemes, or between open and closed varieties of /e/ ~ /ɛ/ and /o/ ~ /ɔ/.

The Order of the Letters

In the North-West Semitic alphabet, the letters had a specific order. The Phoenician alphabet eliminated certain letters from the original model (*see* **Ugaritic**), but the basic order was otherwise left intact (see Table 3). Greek follows the Phoenician order with little or no change. In the earliest Euboian abecedaria (found in Italy, and to become the model for the Etruscan alphabet), the two sibilants Ξ (written ⊞) and sán (M), which were not used in Euboian writing itself, are included in the spots for Phoenician *samk and *ts'adɛː. This has understandably led to the supposition that the letter sán somehow continues

Table 3 Semitic and Greek alphabetical order and numerical values

Semitic ts'adê. However, neither the shape (rotated *šeːn), nor the sound-value (/s/), nor the name of sán (most likely from *samk) gives any support to this thesis. Neither does the spot that sán occupies in the Corinthian alphabet, where it is in the place for sígma, as expected. It is therefore more likely that the Euboian and Corinthian abecedaria simply reflect that the existence of letters at places 15 and/or 18 in the Phoenician model was known to the Greeks, but that the actual names, sound-values, and shapes were confused in different ways. The Euboians borrowed the Corinthian shape of sígma (= sán) to fill one of the slots, the Corinthians filled the hole left by *ts'adɛː with the shape of *samk (pronounced like *šeːn). The Ionians simply forgot about the shape, sound-value, and alphabetical slot of *ts'adɛː altogether, and when a letter with a similar sound-value /ts/ was adopted at Miletos, sámpi was appended at the end of the alphabet (and, indeed, sámpi has no relationship to *ts'adɛː).

Appending new letters at the end of the alphabet, leaving the previous ordering intact, was standard procedure. We can, therefore, use the alphabetical order as an indication of the order in which supplemental letters were added. This confirms what is already clear from the distribution of the signs: the letter Y /u/, used in every variant of the Greek alphabet, was the first addition. The letters Φ and X/Ψ (used everywhere but Crete, Thera, and Melos) come next, but sometimes the order is XΦ, sometimes the order is ΦX. We can deduce that both signs were added simultaneously. Next, if applicable, comes the second variant of X/Ψ, which means of course that the letter was split into two entities at a later time. Ionia added further letters after that: first omega, then sampi. Other additional letters elsewhere may also have been appended at the end (e.g., Corinthian ϡ = /ɛ(ː)/), but we have no evidence.

J. Naveh interprets these striking paleographic differences as evidence that the Greek alphabet was borrowed from Phoenician at a time (12th or 11th centuries B.C.E.) when Phoenician writing also exhibited most of these characteristics.

Naveh's argument has been used as supportive evidence in the 'New Chronology' debate (e.g., by James, 1991). However, as we have seen, the Greek shape of the letters káppa, mûː, and délta all point towards a transmission around the year 850 B.C.E., and Naveh has to admit as much at least for káppa, which, in his view, was reborrowed from Phoenician in the 9th century B.C.E. (while the old shape hung on as Greek ↓ /k^h/). Similarly, Naveh suggests that *waw was borrowed first as the shape that was eventually transformed into Greek ϝ, and that ϝ was reborrowed in the 9th century.

But those are unnecessary complications. There is nothing in the Greek script as we find it in the 8th century that is inconsistent with 9th-century Phoenician writing. The difference in style is merely a consequence of the novelty of alphabetic writing in Greece: shapes, names, and sound values were distorted in the process of adaptation from Phoenician to Greek, and further, in the island-hopping from one Greek epichoric variant to another. The Greeks seem to have understood well enough that writing ran from right to left in single-line inscriptions, but either their Phoenician teachers never got to the point of explaining what to do in multiline inscriptions, or their Greek pupils forgot about that lesson. Less lapidary and more cursive writing, as well as standardization of the shapes, were still centuries away in Greece, as they had been in Phoenician writing itself a couple of centuries before. In the end, Greek writing, unlike the Phoenician and the Phoenician-derived scripts (and also unlike Greek-derived Lydian and Etruscan), settled on left to right directionality.

The Direction of Writing

By the 9th century B.C.E., the Phoenician alphabet had reached a certain level of stability and standardization: there were few regional and/or personal variations anymore in the shape of the letters, and the script was uniformly written from right to left. The style was becoming more and more fluid and cursive. By contrast, Greek writing in the 8th and subsequent centuries, until the standardization of the Ionian script in the 4th century, had very different characteristics: regional and personal variations in the shape and orientation of the letters abound, the inscriptions run from right to left, or from left to right, or in *boustrophedon* fashion ('as the ox plows,' i.e., right to left in one line, left to right in the next, etc.).

The Greek Epichoric Alphabets

The Greek regional (epichoric) alphabetic variants are subclassified according to a colorful naming scheme that derives from a map in Kirchhoff's 1863 work on the Greek alphabet (see **Figure 1**). The 'primitive' alphabets of Crete, Thera, and Melos are called 'green,' the 'Western' alphabets of, for example, Euboia and Lakonia, are called 'red,' and the 'Eastern' alphabets of Ionia, but also of Corinth and neighboring city states, are called 'blue.'

In the following, green is used to stand for certain primitive characteristics (found in Crete, Thera, or Melos, but not only there), red and blue for the typical Western (X=/ks/, Ψ=/k^h/) and Eastern (X=/k^h/, Ψ=/ps/) varieties, respectively, and the term 'white' for variants that are intermediate between red and blue.

Figure 1 Greek epichoric alphabets.

The main characteristics of the green variants are:

- 'crooked' iota ϛ, ꞃ, and san ϻ (Crete, Thera, Melos; Corinth/Isthmus; Akhaia, Aitolia, Ithaka);
- archaic varieties of B, such as ß, ᛋ, ᛒ, and ᚹ (Crete, Thera, Melos; Cyclades; Corinth/Isthmus);
- five-stroke ϻ ᛗ (Crete, Melos; Euboia);
- archaic varieties of F ᚠ, H ᚼ, and Q ᚩ (Crete);
- absence of supplemental letters after Y (Crete, Thera, Melos).

It should be noted that such **non**primitive shapes as ß, ᛗ, ᚠ, ⊟, and ᚩ are also found in Crete.

The red variants typically have:

- 'Latin-like' Γ (C), Δ (D), Ρ (R), Υ (V);
- Absence of Ξ;
- X =/ks/, Ψ = /k^h/.

The blue variants tend to have:

- Turned lambda (ᛦ);
- X = /kh/, Ψ = /ps/;
- (Ionia) additional letter Ω.

The shapes of Γ/Λ, Δ/Ρ, and Y are not fundamental for the division of the Greek epichoric alphabets into red and blue varieties (although they are relevant for Latin C/L, D/R and V, derived from a red Euboian model). The fundamental difference between the variants is the spelling of the sounds /p^h/, /k^h/, and of the clusters /ps/, /ks/ (see Figure 1).

Many things have been said about the origin of the supplementals X, Φ, Ψ, and about the origin of the red and blue variants. Wilamowitz's ingenious explanation is that Φ and X are both derived from the one aspirate ⊕ /t^h/ that already had a symbol adapted from the Phoenician: Φ by eliminating the horizontal bar, X by eliminating the surrounding circle. Ψ, however, is weakly explained as adapted from Y /u/. The variant ↓ has been explained as deriving from early Phoenician ↓/k/. At the risk of adding one more item to the long list of explanations, I would like to suggest the following, strangely overlooked possibility: it stands to reason that a letter for denoting the phoneme /p^h/ would have involved the existing letter /p/, and that a

letter for denoting the phoneme /k^h/ would have involved /k/. Rather than inventing a whole new symbol, the preferred method for fixing defective writing systems is to modify an existing symbol (e.g., Latin C > G) or to use a digraph (Medieval Latin V V > W). Now double-P would have given a symbol looking approximately like ⊤ or φ (qóppa then becoming φ), double-K would have given ⋔, subsequently simplified to ⋔ or to ⋔ / ⋔.

In any case, there can be little doubt that ⋔, ⋔, ⋔, ⋔, + are all variants of a single sign originally denoting the velar aspirate /k^h/. Except in the green area, and on Naxos, the clusters /ks/ and /ps/ (phonetically perhaps [k^hs] and [p^hs]) started to be written using the new signs as ⋔⋔/⋔⋔ and φ⋔. This is what I call the white system. However, /ks/ could in some parts at least also be written using the Phoenician sign ⋔. The emergence of the red and blue systems is a matter of simplification and removal of digraphs: in the red zone, the system was simplified by abbreviating ⋔⋔ to ⋔, and reserving the variants ⋔ and ⋔ for the aspirate /k^h/. In the blue zone, ⋔ replaced ⋔⋔ (or perhaps an already simplified spelling ⋔), and the symbol ⋔ was assigned a whole new value /ps/, replacing the original digraph spelling φ⋔. The latter development (elimination of all digraphs) also occurred in part of the red area, with /ps/ being spelt ⋔ (Lokrides, Arkadia, Akhaia) instead of φ⋔. Schematically:

	1.	2.	3.	4.	5.	6.	7.	8.	9.
/kh/	⋔	⋔	⋔	⋔⋔	⋔	⋔	⋔	⋔	⋔
/ks/	⋔	⋔	⋔⋔	⋔	⋔⋔	⋔	⋔	⋔	⋔
/ph/	⋔	φ	φ	φ	φ	φ	φ	φ	φ
/ps/	⋔	⋔		φ⋔		φ⋔	⋔		⋔

1 = Crete, Thera, Melos (green).
2 = Naxos (transitional green-white)
3 = Ithaka (white A)
4 = Attica, Aigina, Boiotia, Paros (white B)
5 = Rhodos (transitional white-red)
6 = Euboia, Thessaly, Aitolia, Lakonia, etc. (red A)
7 = (Thessaly), Lokrides, Arkadia, Akhaia (red B)
8 = Knidos (red or blue, depending on the origin of the sign ⋔)
9 = Ionia, Delos, Corinth/Isthmus (blue)

The Ionian dialect had no /w/ and no /h/, and this led to the elimination of waû (except as a number) and to the letter H /h/ becoming /ɛː/ by renewed application of the acrophonic principle (hɛːta > ɛːta). For symmetry, this led to the creation of Ω to denote the vowel /ɔː/. Ionian, like most other variants, also dropped the letter qóppa, and thus we arrive at the Classical Greek inventory of 24 letters (for the further development of the Greek alphabet, *see* **Greek, Ancient**).

Anatolia

The first alphabetic scripts of Ancient Anatolia can be classified into two groups. The first consists of clearly Greek-derived alphabets, such as Phrygian, Lycian (usually written left to right), and Lydian (right to left). Besides the Greek-derived signs, Lycian and Lydian also possess a number of supplemental letters to denote native sounds absent from Greek phonology

(see Table 4). The later Pisidian and Pamphylian alphabets lack such supplemental letters, and can be considered merely Greek alphabetic variants used to write local Anatolian languages.

The second group (Sidetic, Carian) is more difficult to classify. The Carian alphabet contains many shapes that are similar or identical to Greek letter shapes, but the pronunciation of most of them bears no relationship to the Greek pronunciation.

Early decipherers were misled by this characteristic of the Carian script: the Greek-looking letters were read with their Greek sound-values, while the non-Greek letters were variously interpreted as syllabic (due to their rather elevated number and vague similarities to the Aegean linear scripts or the Anatolian hieroglyphic script, *see* **Aegean Scripts**) or as supplemental letters in Lycian/Lydian fashion. Neither approach led to much progress in the decipherment of the Carian language. It was only with the work of Kowalski (1975) and especially Ray (1982) that the decisive first step towards decipherment was taken, by focusing on the Carian-Egyptian bilinguals (especially the onomastic elements therein, cf., the decipherment of Egyptian itself by Champollion) and deriving the Carian sound-values (at first) solely from that evidence, without preconceptions about the sound-values of the letters. Ray's early work was extended further by Adiego (1993), Schürr (1992), and Ray himself (1990), resulting in the identification of all the more common Carian signs, as outlined in Table 5.

The new sound-values of Carian suggest an interesting question: can the Carian alphabet be called Greek-derived, or is the relation more like that between the Latin alphabet and Sequoyah's Cherokee script (see)? Of the five clear shape–sound correspondences between Carian and Greek, the vowels A, O, and Y are strongly suggestive of Greek origin (this also invalidates the possibility of a direct Phoenician-Carian link). Moreover, the Cherokee script is a syllabary, while Carian is alphabetic, arguing against a 'naive' origin of Carian writing. It seems preferable to think (Adiego, 1993) that the shapes derive from a Greek model after all, having passed through a process of cursivization and remonumentalization (e.g., Greek T > Carian ⲧ), although the exact details would need to be worked out further.

(see Table 6) are derived from the Etruscan, which was in turn adapted from an Euboian Greek model (through the Euboian/Chalkidian colony at Kyme).

Etruscan had no voiced stops, just voiceless and aspirated ones. The letters /b/ and /d/ were retained in abecedaria, but not used for writing Etruscan. The letter > came to be used to write the front allophones of /k/, just as Ϙ, following the Greek model, was used to write the back allophones of /k/. Since Etruscan also lacked the vowel /o/ (likewise retained only in the abecedaria), this resulted in the spellings KA, CE, CI, QU, which are also found in early Latin (which added CO, and later settled on CA instead of KA).

Etruscan had the fricatives /f/, /ts/, /s/, /ʃ/, and /h/ (/x/). The first was written as <wh>, 𐌅𐌗 later with a special sign 𐌆 or 𐌇 which Etruscan, remarkably, shares with Lydian. For voiceless /ts/, Greek 𐌶 was used. To distinguish the two sibilants /s/ and /ʃ/, the letters sígma and sán (rarely kseî) were used, as inherited from the Euboian abecedaria. Southern Etruscan used 𐌢 for /ʃ/, 𐌣 for /s/; Northern Etruscan adopted the opposite convention.

The Oscan script shows its Etruscan roots by being written right to left, having no O (the sign 𐌥 <ú>, a modified /u/, is used instead), the sound-value /ts/ for 𐌶, and /f/ written 8. Besides 𐌥, Oscan also uses 𐌹·(𐌷) or ·𐌹 (𐌻) <í> to denote the closed vowel /e/ (besides open /ɛ/ written 𐌴 𐌺).

Umbrian, known principally from a single inscription, the Iguvine tables, is similar to Oscan. It is written right to left, has no O (V or sometimes 𐌰 is written instead). 𐌶 (Z) and 8 are pronounced as in Oscan (and Etruscan). Additionally, Umbrian does not use the letters C and D (although the symbol 𐌿 ř, from etymological */d/, possibly derives from D). Umbrian also writes the shibilant /ʃ/ as 𐌢, like (Southern) Etruscan. Besides 𐌿 ř, Umbrian also has the additional letter 𐌼 ç (etymologically from palatalized */k/).

Other scripts from Central and Southern Italy (Northern and Southern Picene, Middle Adriatic) largely follow the Oscan and Umbrian model, with some minor graphic variations (e.g., the dotted forms 𐌰 = A, · = O, 𐌹 = T, and : = 𐌇, and the variants 𐌥 ú, 𐌹 í).

The Northern scripts (Venetic, Lepontic, Gallic, and Rhaetic) also show Etruscan influence: they are mostly written right to left, lack B and D, use C for /k/ and 𐌢 for /ʃ/. The vowel O is present, however. Venetic uses WH to denote /f/, and the voiced stops /b/, /d/, and /g/ are written 𐌑 ⟨p^h⟩, 𐌶 ⟨z⟩, 𐌺 ⟨k^h⟩. This Northern Etruscan alphabet spread beyond the Alps, and became one of the influences on the Germanic *futhark* (*see* **Runes**).

The Latin (Roman) alphabet shows Etruscan influence in its use of C for /k/, and in the early spelling FH for /f/ (this has in fact become unattested, with the exposure of the Praenestine fibula as a fake). Early inscriptions were written right to left, but Latin soon standardized on left to right directionality. The letters B, D, and O were recovered with their Greek values from the Etruscan abecedaria, but the phoneme /g/ was not distinguished from C /k/ until 234 B.C.E., when the modified form G was adopted to denote the voiced stop. This new letter took the place of Z (/ts/) in the abecedarium, for which the Latin language did not have much use. A further Roman innovation was the simplification of the digraph FH /f/ to F, which meant that the vowel /u/ and the semivowel /w/ both came to be written V (in itself an arrangement no different than the writing I for both vowel /i/ and semivowel /j/, as inherited from Etruscan and, ultimately, Greek).

The letters Y and Z were introduced in the early Imperial period, to transcribe the sounds /y/ and /zd/ (or /z/) in Greek borrowings. The Emperor Claudius further introduced the signs ↃΨ /ps/, Ⅎ /w/ or /v/, and ├ for a vowel intermediate between /i/ and /u/ (*maximus* ~ *maxumus*), perhaps simply /ə/, but these were quickly abandoned after his death.

The names of the letters did not make the transition from Greece to Italy. We do not know what the Etruscans called their letters, but it seems likely that the Roman naming system was taken over from them. This system makes a distinction between letters that cannot be pronounced in isolation (the stops) and the other letters. The stops are named by adding the vowel /e/ to the consonant (BE, CE, DE, GE, PE, TE), except allophonic KA and QU, which add the vowel with which they were always associated in Etruscan usage. Vowels are named after themselves (A, E, I, O, U), while sonorants and fricatives originally were too (/ff/, /ll/, /mm/, /nn/, /rr/, /ss/, /kss/), as witnessed by the fact that the early Roman letter names, being asyllabic, could not be mentioned in poetry. Later, /e/ was preposed, and sometimes /e/ appended, resulting in the names ef(fe), el(le), em(me), en(ne), er(re), es(se), ex(e), the latter later also pronounced /iks/. Only /h/ could not be pronounced in isolation (/hh/ was impossible in Latin, unlike perhaps in Etruscan, where the sound may have been /x/ or /χ/), so it acquired the name /ha/ (and later *hac* to distinguish it from the vowel /a/, after the loss of Latin /h/). The Greek letters Y and Z were borrowed with their Greek names as ypsilon (or *i graeca*) and *zeta* (or *zet*). (For the further development of the Roman script, *see* **Latin**.)

Europe as a Linguistic Area

T Stolz, Universität Bremen, Bremen, Germany

Historical Overview

Areal linguistics of Europe is currently experiencing a period of intensive empirical research and methodological discussion, as the impressive series of eight volumes resulting from the EUROTYP project (Bossong and Comrie, 1998–2003) and other publications either directly (Bernini and Ramat, 1992) or indirectly (Mayerthaler *et al*., 1993) related to it amply document. Among their early predecessors in the 19th century, we find the German Indo-Europeanists Schleicher (1850) and Pott (1868; 1887), whose interest in the linguistics of Europe, however, was not primarily guided by purely geolinguistic hypotheses but rather by the prominence given to questions of language genealogy induced by the *Zeitgeist* of their epoch. Therefore, their studies highlighted diversity rather than convergence – an attitude that continued to dominate well into the 1960s among scholars studying the European linguistic landscape. In the mid-20th century, Lewy ([1942] 1964), most probably inspired by the 'discovery' of the Balkan *Sprachbund* by Sandfeld (1930) and the large phonological areas proposed by prominent members of the Prague Linguistic Circle in the 1930s (Jakobson, [1931] 1971), looked at the areal makeup of Europe, mostly in the realm of morphology and morphosyntax. Lewy's fundamental ideas are also at the heart of the contributions by Becker (1948), Wagner (1959; 1964) and Décsy ([1973] 2000), who, in a manner of speaking, are the representatives of a still somewhat speculative and impressionistic approach with strong affinities to *Völkerpsychologie*, the formerly widespread branch of cultural anthropology that, anticipating Whorf ([1941] 1956) in a way, postulated a high degree of cognitive relativism supposedly determined by and

Europe as a Linguistic Area

Historical Overview

Areal linguistics of Europe is currently experiencing a period of intensive empirical research and methodological discussion, as the impressive series of eight volumes resulting from the EUROTYP project (Bossong and Comrie, 1998–2003) and other publications either directly (Bernini and Ramat, 1992) or indirectly (Mayerthaler *et al*., 1993) related to it amply document. Among their early predecessors in the 19th century, we find the German Indo-Europeanists Schleicher (1850) and Pott (1868; 1887), whose interest in the linguistics of Europe, however, was not primarily guided by purely geolinguistic hypotheses but rather by the prominence given to questions of language genealogy induced by the *Zeitgeist* of their epoch. Therefore, their studies highlighted diversity rather than convergence – an attitude that continued to dominate well into the 1960s among scholars studying the European linguistic landscape. In the mid-20th century, Lewy ([1942] 1964), most probably inspired by the 'discovery' of the Balkan *Sprachbund* by Sandfeld (1930) and the large phonological areas proposed by prominent members of the Prague Linguistic Circle in the 1930s (Jakobson, [1931] 1971), looked at the areal makeup of Europe, mostly in the realm of morphology and morphosyntax. Lewy's fundamental ideas are also at the heart of the contributions by Becker (1948), Wagner (1959; 1964) and Décsy ([1973] 2000), who, in a manner of speaking, are the representatives of a still somewhat speculative and impressionistic approach with strong affinities to *Völkerpsychologie*, the formerly widespread branch of cultural anthropology that, anticipating Whorf ([1941] 1956) in a way, postulated a high degree of cognitive relativism supposedly determined by and

identifiable on the basis of linguistic structure. Becker (1948) turned his attention to the overall convergence of European languages, while Décsy ([1973] 2000) tried to combine the identification of distinct subareas (= diversity) with the deduction of pan-Europeanisms (= convergence), cf. below.

The three booklets by Haarmann (1976a; 1976b; 1977) mark the transition from heavy speculation to a more rigorous methodology mostly rooted in quantitative typology, whereas Bechert ([1981] 1998), evidently impressed by the progress areal linguistics had been making in the description of the linguistic geography of regions outside of Europe, instigated an entire research program for the investigation of Europe as a linguistic area, thus preparing the ground for EUROTYP (König and Haspelmath 1999). More recently, a new approach, meant as a kind of transnational philology, has been developing. It goes by the name of *Eurolinguistik,* and, apart from the clearly cultural–political mission the major representatives have formulated, adopts a pan-European vantage point and attempts to identify those linguistic phenomena that attest to a kind of common Europeanness of the languages and speech communities involved. A recent example is Hinrichs's (2004) collection of articles that address the issue of whether the languages of Europe are currently shifting from the synthetic morphological type to the analytic type. For other linguistic endeavors with a continent-wide orientation, the reader is referred to the survey in Ureland (2004).

There is thus, an abundance of studies dedicated to the description and evaluation of the geolinguistic situation in Europe. Indeed, these studies all contribute to our knowledge of the areal linguistics of the continent. However, they stem from a variety of schools of thought with at times widely diverging theoretical axioms. This diversity on the theoretical side, of course, has methodological consequences that, in turn, also determine which picture of areality results from the interpretation of the empirical facts.

Approaches

In addition to the commented inventories of European languages without explicit or dominant areal-linguistic goals (Nocentini, 2002; Banfi and Grandi, 2003), there are several approaches to the languages of Europe that all have been adopted at least once in the history of areal linguistics of Europe. The egalitarian approach, the segregating approach, and the center vs. periphery approach are each discussed separately, with these terms being coined here as handy labels for the present occasion. Before we proceed to this survey, some remarks of a methodological nature are in order that affect not just European areal linguistics specifically but areal linguistics in general (including subareas, etc.). For a more detailed discussion of these and similar problems, see the contributions in Matras *et al.* (2005).

With a view to establishing whether or not the distribution of linguistic phenomena over languages has or needs an areal explanation, it is absolutely necessary to clarify in advance a number of difficult issues. First of all, one has to start from somewhere, that is, one has to decide whether the area-to-be has a geographic, political, historical, cultural, or other foundation. Talking about Europe as a linguistic area presupposes an idea of some kind of what is meant by 'Europe.' If the starting point is geography, problems arise, as Europe is notoriously difficult when it comes to determining, for instance, where it ends and Asia begins and vice versa. A frequent victim of these uncertainties about the borders separating the two continents is the Caucasian region, which is often totally or partially (= Trans-Caucasus) ignored (Décsy, [1973] 2000), whereas languages such as Georgian, (Eastern) Armenian, Azeri (South Azerbaijani), and so on are classified as 'European' in other publications (Siewierska, 1998). A perhaps rhetorical question: If the Caucasus and/or Ural mountain ranges are considered topographic obstacles that supposedly render communication across the line difficult, why should this be different in the case of the Alps? As a matter of fact, individual researchers arbitrarily stipulate certain relatively time-stable landmarks as outer boundaries of the continent, even if one and the same language is spoken on both sides of the landmark. One example is the Bosporus, which cuts the Turkish territory into two parts of very different size, the smaller one belonging to Europe, while the larger one forms part of Asia. Does it make sense at all for areal linguistics to follow the lead of geography, especially if the solutions of the latter are inconclusive or variable? These varying solutions do not only have implications for the sample size but also for the general inventory of possible structural properties of European languages and the quantity and quality of potential subareas.

Similarly, taking political boundaries as a yardstick creates more problems than it solves, although it must be acknowledged that they may become relatively strong secondary factors in the reshaping of linguistic boundaries, especially dialect boundaries (Auer, 2004). Since state boundaries do not automatically map onto topographic landmarks of the above-mentioned kind, a political definition of 'Europe' yields a result markedly different from a geographic definition. Under the premise that the notion of 'Europe' is not reduced to the present member states

of the European Union, Turkey may again serve as an example of the potential problems a policy-based definition is bound to create: If the entire territory of the Turkish state has to be taken into account, this also means that those languages that are coterritorial with Turkish, such as Kurdish, become European languages. Varieties of Kurdish, however, are also spoken in the adjacent countries of the Middle East – a fact that makes them Asian languages – and thus the political boundary induces the linguist to investigate only part of the territory occupied by a given speech community.

What is more, political boundaries are of course subject to minor and major adjustments according to the momentary balance of power among competing political entities. In other words, the supposed European linguistic area based on political boundaries is prone to metamorphosis in time, as its political basis is in no way immutable. Thus, if we go back a couple of centuries and look at the political boundaries of the *de jure* predecessor of contemporary Turkey, the Ottoman Empire, the option of including or excluding it from the study of Europe as a linguistic area in say, the 17th century, is tantamount to deciding whether to have a sizable part of the Middle East and North Africa in or out of the sample. If the answer is to exclude, then the entire Balkans and other regions and their languages have to be excluded as well because they were under Ottoman rule at that time – a solution that leaves room only for a rather small-sized Europe.

Equally unhandy is the requirement of a common cultural background of those speech communities whose languages belong to one and the same linguistic area (Décsy, [1973] 2000). One would have to define a culture area beforehand and thus work on the hypothesis that culture areas and linguistic areas are largely coextensive with each other (Lewy, [1942] 1964; Becker, 1948). Haarmann (1976b: 71–76) demonstrates that the culture-first approach rests on the erroneous assumption that cultural convergence and linguistic convergence are two sides of the same coin, which is evidently much too strong a hypothesis. Apart from the fact that it would surely cause problems to depict Europe sweepingly as culturally homogeneous, it must be stated that cultural traits and linguistic traits may diffuse over geographic boundaries, but not necessarily in a parallel fashion. On the other hand, neither of the two kinds of traits automatically covers a geographically defined region in its entirety. Thus, instead of starting from mostly elusive or controversial nonlinguistic criteria, the more promising approach to linguistic areality is the one suggested by Bechert ([1981] 1998), according to which the diffusion patterns of the individual linguistic phenomena, independent of geographic, cultural, and political assumptions, should guide the linguist. This is what generations of dialectologists have successfully been doing when they identify isoglosses and define dialects as those varieties that share a certain set of isoglosses (or isopleths, i.e., clusters of isoglosses) (van der Auwera, 1998).

Equally important for the outcome of one's research is the status of the sample languages. The exclusive comparison of written varieties of normative standard languages will inevitably yield results different than an approach that takes nonstandard varieties (regional languages, dialects, etc.) into account (Haarmann, 1986). Recent research emphasizes the fact that we need to pay more attention to substandard varieties in order to better understand – among other things – the areality of linguistic phenomena (Kortmann, 2004). With these provisos in mind, we are now in a position to tackle the issue of the coexistence of various approaches.

The Egalitarian Approach

The egalitarian approach presupposes that all languages that qualify as European share certain features and thus display a sufficient degree of similarity, such that the entire geographic space occupied by these languages can be considered a linguistic area. Therefore, this approach adopts *per se* a continent-wide perspective. The most radical version of the egalitarian approach can be found in Becker (1948), who treats the languages of Europe as a solid homogeneous block. The evidence for this is, however, rather poor and consists mainly of idiomatic or phraseological parallels with a more or less obvious origin in Christian religious discourse practices. Décsy ([1973] 2000) is slightly more cautious, as he also recognizes that Europe is fragmented into several subareas and thus that there is a potentially rather high degree of heterogeneity of the continent. This acknowledged internal diversity notwithstanding, Décsy ([1973] 2000) searches for pan-European commonalities that he terms 'Europemes.' Among these Europemes, we encounter, for instance, a kind of common core phonological system with five vowels (= /a/, /e/, /o/, /i/, /u/) and 10 consonants (/p/, /t/, /k/, /s/, /v/, /m/, /n/, /l/, /r/, /j/) that are said to be present in each and every phonological system in Europe – a somewhat dubious assumption. For reasons of space, the tenability of Décsy's hypotheses is not reviewed here (but see Stolz, 2002). Since the identification of full-blown Europemes (in the sense of exceptionless substantial areal traits) on all linguistic levels is, for various reasons, next to impossible, Décsy ([1973] 2000: 341) resorts to a solution reminiscent of Lewy ([1942] 1964: 103–108) and Becker (1948) when he says:

> [t]he genuine resemblance [of the languages of Europe] lies however in the way of thinking [...]. [T]he great majority of Europeans hold the same mind-set, which arose from a Graeco–Latin cultural tradition in a two-thousand year development, connecting the regions between Iceland and the Urals, between the North Cape and Palermo, between Dublin and Istanbul to a unity in historical proportion.

This is equivalent to a declaration of defeat in linguistic terms because it admits that one cannot find sufficient tangible proof of a pan-European linguistic structure.

Haarmann (1976a: 105–106) adopts the notion of Europeme but defines it more rigorously in analogy to the well-established Greenbergian probabilistic universals. Haarmann (1976a: 107–108) goes on to sketch the methodological and empirical requirements necessary for a wholesale comparison of the languages of Europe. On a still provisional basis of selected aspects of 65 sample languages excluding the Caucasian region (the ultimate goal being the large-scale comparison of entire grammatical systems), Haarmann (1976a: 108–116) puts forward 16 Europemes for which he feels to have sufficient evidence (the following Europemes implicitly contain the common introductory phrase 'In all European languages,' or a suitable variation thereof; where the Europemes come in the shape of an implication, it is always meant to be unilateral):

- Europeme 1: The number of simple phonemes ranges between 10 and 110.
- Europeme 2: Consonants outnumber vowels.
- Europeme 3: Only one-third of the potential phonotactic combinations is actually made use of.
- Europeme 4: The basic syllable structure is (C)V(C)(C).
- Europeme 5: The basic morphotactic structure is

  [radical](-[derivation]) (-[inflection])

- Europeme 6: Singular and plural are distinguished formally.
- Europeme 7: Nouns and verbs are distinguished formally.
- Europeme 8: Present and past tense are distinguished formally.
- Europeme 9: Morphological case distinctions range from zero to 30.
- Europeme 10: Indicative, imperative, and conditional are distinguished formally.
- Europeme 11: Multifunctional derivational affixes are ubiquitous and outnumber monofunctional ones.
- Europeme 12: Synthetic and analytic encoding strategies are compatible with each other.
- Europeme 13: Changes from synthetic to analytic structures do not necessarily embrace the whole grammatical system.
- Europeme 14: The order S > O is basic (V may occupy various positions).
- Europeme 15: VSO languages employ the category of verbal nouns.
- Europeme 16: Intonation contours in questions are different from the ones used in declarative sentences.

Some of the above generalizations are almost trivial because they meet universal expectations. Others are not particularly distinctive, and still others remain somewhat vague as they circumscribe the range of variation between a minimum and a maximum number of entities. Already Europeme 1 is problematic, as the upper limit is imposed by Kildin Saami, with whose large phoneme inventory of over 100 none of the other European languages can compete (there is a gap of over 40 units between Kildin–Saami and the second best, Lithuanian). At the same time, it remains opaque which of the languages of Haarmann's sample comes close to the minimal size of phoneme inventories, as Haarmann (1976a: 113) himself states that European languages generally do not display significantly small inventories. Similarly, the rich morphological case-systems suggested by Europeme 9 boil down to Hungarian, which, according to the maximalist count, displays 28 cases and thus exceeds the paradigms of its competitors (Finnish, Basque) by about a dozen units. Instead of working with the statistical extremes, it would probably have made more sense to go by the statistical mean or any other mathematical procedure on which predictions about the expected average system can be formulated. The Europemes allowing for quantitative variation therefore can be considered to be merely observations of structural facts that cannot claim to identify a certain quality that characterizes the languages of Europe. In addition, Europeme 13 is odd in the sense that it is the only diachronic generalization in a list of otherwise strictly synchronic observations, and Europeme 15 has a genetic bias as it only applies to members of the Celtic phylum.

No matter how accurately the Europemes capture the linguistic facts, Haarmann's (1976a) approach works in such a way that the languages of his sample are automatically treated as similar in one way or another (which is a pitfall of the geography-first approach criticized by Haarmann (1976b) himself). This is for methodological reasons: The researcher focuses on the common denominators alone without specifying whether or not the findings have to be explained by diffusion. Any two languages of the

world, past and present, can be compared in order to determine what they have in common. Whether the shared properties call for a genetic, typological, areal, or other explanation, if at all, is a completely different matter. Thus, the above Europemes gain significance for areal linguistics if and only if it can be demonstrated that they result from diffusion (either way, i.e., receding or expanding) and/or that their combination is characteristic of the area under scrutiny such that it can be kept apart from other areas.

The Segregating Approach

The segregating approach starts from a different premise, according to which not all European languages resemble each other to the same extent; the degree of similarity may be significantly stronger in certain smaller subareas of the continent that, in turn, deserve the designation of distinct linguistic areas of their own. Thus, this approach favors research on individual regions, not necessarily with an orientation toward comparing the findings with those of other potential subareas. Haarmann (1976b), and to a lesser extent Décsy ([1973] 2000), are exceptions as they, in principle, combine the segregating and the egalitarian approaches.

On the basis of a sample of 18 languages, Lewy ([1942] 1964) distinguishes five subareas in Europe. The languages discussed are to be understood as representatives of larger groups forming geographic neighborhoods:

- Atlantic area (Celtic, Romance [without Rumanian (**Romanian**)], East and West Scandinavian, English)
- Central area (German, Hungarian)
- Balkan area (Albanian, Rumanian, Greek)
- Eastern area (Baltic, East Slavic, Finnish, Mari, Mordvin (Erzya))
- Arctic area (Yurak)

With the notable exception of the Balkan area, Lewy's proposals have experienced major alterations in the subsequent years. The changes are partly occasioned by the fact that the number of sample languages increased considerably from 65 in Décsy's and Haarmann's publications in the 1970s to 140 or more for EUROTYP and related projects. The more important factor, however, is the introduction on the list of items to be compared of further categories and phenomena on all linguistic levels. Presently, 12 potential subareas (often called *Sprachbünde* or the like) are discussed with varying intensity in the pertinent literature, even though most of them are still largely controversial and some – like the Littoral *Sprachbund* – are unlikely to pass the test at all. In the following list, the languages that count as members of a given subarea are the ones explicitly mentioned by the first source quoted; in the literature, different sets of languages may occur under the same heading, whereas different labels may be used for the same set of languages. This variation reflects the fact that the shape of a linguistic area is directly dependent on the quality and quantity of the features one scrutinizes (Haspelmath, 2001: 1505).

- Standard Average European (SAE) languages (= Albanian, Dutch, French, German, Italian, Portuguese, Sardinian, Spanish) (Haspelmath, 2001) including the *Charlemagne-Sprachbund* (van der Auwera, 1998: 824); cf. below.
- Viking *Bund* (Décsy, [1973] 2000)/northwest linguistic area (Wagner, 1964) (= insular and mainland North Germanic, Celtic, Saami, Finnish, Veps, and the Anglo-Saxon component in modern English)
- British (Isles) areal type (= Celtic, English) (Wagner, 1959), the relic of an erstwhile more extended area to which also Basque and Berber belonged
- Littoral *Bund* (= Basque, Dutch, Frisian, Maltese, Portuguese, Spanish) (Décsy, [1973] 2000), based on the idea that the speech communities involved represent renowned seafaring nations
- Mediterranean linguistic area (= Romance, Maltese, North African Arabic, Hebrew, Turkish, Balkan *Sprachbund*, Serbian, Croatian, Slovenian) (Ramat and Stolz, 2002)
- Rokytno *Bund* (= Bielarusian (**Belarusan**), Kashubian, Lithuanian, Polish, Ukrainian) (Décsy, [1973] 2000)
- (Circum-)Baltic super-position zone (Koptjevskaja-Tamm and Wälchli, 2001)/ Peipus *Bund* (Décsy, [1973] 2000) (= Balto–Finnic, Danish, Estonian, Latvian, Lithuanian, Low German (**Low Saxon**), Saami, Swedish)
- Karelian *Sprachbund* (Sarhimaa, 1991) (= Russian, Balto–Finnic)
- Eurasian *Sprachbund* (East Slavic, conservative Polish and Sorbian, Rumanian, Lithuanian, Altaic languages of the former Soviet Union) (Stadnik, 2002)
- Danube *Sprachbund* (= Czech, German, Hungarian, Slovak) (Skalička, 1968)
- Volga–Kama *Sprachbund* (= Bashkir, Chuvash, Kalmyk (Kalmyk-Oirat), Mari, Mordvin, Tatar, Votyak (Udmurt), Yurak (Nenets), **Komi–Zyrian**) (Wintschalek, 1993)
- Caucasian *Sprachbund* (= all Caucasian phyla) (Haarmann, 1977)

Décsy ([1973] 2000) does not tolerate a single European language to remain outside a *Bund,* and thus he postulates a number of so-called groups of languages (viz., Isolates [in the sense of 'not belonging to any other *Bund*'] and Diaspora languages) that have no areal raison d'être but are said to be based on social and/or historical criteria. Haarmann (1976b) rightly observes that this *horror vacui* of Décsy's renders the whole areal undertaking dubious since the classificatory criteria are not kept constant, which is characteristic of Décsy's handling of the problems posed by European areal linguistics (Russian, for instance, counts as an SAE language just because it happens to have more than 50 million speakers; thus, demographic criteria may oust structural ones for Décsy). Moreover, languages do not have to converge even though they happen to be neighbors. The fact that the territories of two speech communities adjoin surely facilitates convergence but does not necessarily trigger it. Irrespective of these additional methodological problems, the many and sometimes competing suggestions of subareas within and beyond Europe are indicative of a certain linguistic heterogeneity of the continent. This heterogeneity on the meso level and micro level raises the question of whether it makes sense at all to talk about Europe as a linguistic area on the macro level.

Center vs. Periphery Approach

The center vs. periphery approach is not so much a compromise between the two previous ones (which operate on the basis of predetermined areas with more or less fixed sets of member languages) as it takes a dialectology-minded stance. It assumes that individual linguistic phenomena diffuse geographically in such a way that it becomes difficult to determine clear-cut boundaries between those languages that form part of a given linguistic area and those that remain outsiders. Membership in a linguistic area is thus a matter of degree, a gradient property of the languages compared (Haspelmath, 2001). The approach is feature based with a continent-wide perspective (or more precisely, with a potentially unlimited perspective, as no boundaries are defined beforehand). This approach plays an important role in the recent discussion about the notion of SAE languages.

Haspelmath (2001: 1493–1501) presents a list of 12 properties that he classifies as major SAE features, all of which belong to the realm of morphosyntax in the widest sense of the term. In the subsequent list of features, the abbreviation 'SAE' stands for varying sets of languages that nevertheless overlap in such a way that some languages partake in (almost) every SAE-isogloss (namely French and German, the two pillars of the *Charlemagne Sprachbund*):

- presence vs. absence of definite and indefinite articles: SAE languages have both types of articles, whereas languages on the fringes of and beyond the SAE area either lack one or both.
- relative pronoun strategy in relativization: SAE languages employ relative pronouns, i.e., relativizers that contain grammatical information about the syntactic function of the relativized head in the relative clause, whereas outside the SAE area, languages opt for invariable relative particles or other strategies.
- 'have'-perfect: In SAE languages, an auxiliary with the (erstwhile) lexical meaning of 'have' serves the purpose of encoding perfect (sometimes in complementary distribution with 'be'-perfects); non-SAE languages prefer 'be'-perfects or other strategies.
- agent-like experiencers: SAE languages tend to encode experiencers as subjects and thus treat them on a par with agents, whereas languages in the European east and also in the extreme northwestern regions have a predilection for keeping agents and experiencers formally apart; this difference in semanto–syntactic behavior is, however, a matter of degree, as both agent-experiencer 'syncretism' and agent-experiencer 'differentiation' can be encountered on both sides of the dividing line.
- participial passive: SAE languages have a passive construction made up of an auxiliary and a passive participle of the lexical verb, a construction type that is absent from the languages spoken in the eastern part of the continent and in the westernmost languages.
- anticausative–prominence: Inchoative–causative alternations are expressed predominantly by anticausatives in SAE languages, whereas causatives are preferred by languages outside this area; as with agent-experiencer encoding, we are dealing with a preference for anticausatives and not with a 100% solution.
- dative external possessors: SAE languages typically have external possessors and encode them as datives, which contrasts with external possessors of the locative type found in North Germanic and with languages that lack external possessors altogether.
- negative pronouns/lack of verbal negation: SAE languages normally combine a verb unmarked for polarity with a negative indefinite pronoun, while outside this area, i.e., on the western and eastern rims of the continent, negative pronouns go along with negated verb forms.

- particle comparatives: SAE languages overwhelmingly employ particle comparatives, i.e., the standard of a comparative construction is introduced by a conjunction-like element; in other European languages, the locative strategy of marking the standard is more frequent.
- equative constructions based on the relative clause: Equally in the realm of comparison, equative constructions reveal that SAE languages resort to a kind of adverbial relative clause that contains the standard of comparison; this strategy is unknown in the languages spoken in the west, north, and east of Europe, where special equative markers or other means are employed.
- strict agreement markers: SAE languages inflect their verbs for subject person even though an overt subject NP is always copresent (= 'non-prodrop'), whereas the vast majority of European languages are of the referential-agreement type (= 'prodrop').
- intensifier-reflexive differentiation: SAE languages distinguish intensifiers (= words that mark the referent of an NP as central) from reflexives, whereas nondifferentiation of the two categories is widespread among non-SAE languages.

These findings stem from a variety of studies, the empirical basis of which differs widely because of different sample size and so forth. Some of the features have a wider distribution that embraces the bulk of the languages of Europe, whereas others are attested only in a relatively small number of languages. Some are characteristic of European languages in general and let them stand out as 'exotic' (Dahl, 1990), whereas others are preponderantly Indo-European or characterize only a subset of the languages of Europe. Independent of these differences in their distribution in space, the phenomena have one crucial element in common, viz., they all involve larger or smaller geographically contiguous areas. In other words, they do not occur sporadically on the map but cover entire regions (with the occasional isolate or secondary accumulation outside the more extended area). More often than not, the isoglosses cut across major (= macrophyla such as Indo-European and Uralic, etc.) or minor (= phyla and subphyla such as Germanic and Romance, North Germanic and West Germanic, etc.) genetic groups. This is of course indicative of a possible origin in diffusion via language contact.

The various isoglosses overlap, which allows us to identify a core area with a particularly high number of shared features, as opposed to a periphery in which languages only participate in a smaller number of isoglosses. Ideally, the following generalization holds: The further away one gets from the core, the smaller the number of shared features. In a manner of speaking, a given language may be more or less SAE according to the number of isoglosses in which it partakes. Being an SAE language is thus again a matter of degree. However, this observation cannot solve all the problems acknowledged by Haspelmath (2001: 1504–1506). Apart from the fact that the complete absence of shared features may be taken as evidence of a language's areal outsider status, it is the linguists' choice of features that has a bearing on the identification of areas. A different catalogue of properties might yield a completely different geolinguistic map of the same group of languages. Moreover, there remains a certain element of arbitrariness when it comes to deciding what the numbers of attested isoglosses tell the observer. As a matter of fact, it is up to the individual linguist to decide how many features are required for a language to be a member of the core or the periphery – and, on top of that, whether the number of shared features is in any way significant. For the solution of the latter problem, comparative studies of linguistic areas worldwide are called for.

Nevertheless, the validity of the SAE area is well documented and based on empirically solid foundations. In addition to the above major features, Haspelmath (2001: 1501–1504) mentions many further candidates for the status of SAE isogloss; however, their exact geolinguistic distribution has not been established yet. Some of these additional features provide evidence *ex negativo,* as they state the absence of a given feature in SAE languages (lack of grammatically relevant alienability correlations in adnominal possession; lack of formal inclusive–exclusive distinction on pronouns; lack of (partially) reduplicating constructions). Three of these supposedly minor features are discussed below, based on research carried out by the present author. While one may agree with Haspelmath that negative evidence has to be taken into account when it comes to identifying linguistic areas, it is necessary to also accept the methodological consequences. If the absence of certain features is characteristic of SAE languages and is thus counted as an isogloss defining a linguistic area, then the absence of typical SAE features in languages outside the SAE area may likewise be considered evidence *ex negativo* in favor of a linguistic area (especially if the features in question are in a binary nongradient relation). Thus, a strong competitor of the SAE *Sprachbund* is created as an epiphenomenon of our search for isoglosses supporting the SAE hypothesis. It would certainly be unfortunate to baptize this additional area the 'non-SAE area' (not simply because it might ultimately turn out to comprise the majority of the languages of Europe). If one wants to deny those

languages that lie outside the SAE *Sprachbund* the status of an area of their own, it is a necessity to find strong counterarguments, among which only internal heterogeneity seems to be convincing.

The center vs. periphery approach reveals certain important facts. In addition to the idea that membership in a linguistic area is a gradient property, Haspelmath's findings also suggest that one and the same language may belong to several different linguistic areas at the same time (for example, a marginal member of the SAE *Sprachbund* might be a marginal or central member of the still nameless non-SAE competitor). Given that the linguist's choice of features has a considerable influence on what a linguistic area might look like, there is at least theoretically the possibility that the prominence given to SAE languages in the extant literature does not adequately reflect the areal composition of the continent. Chances are that the members of the SAE *Sprachbund* identified so far behave differently as soon as we take other linguistic phenomena into consideration, thus relativizing the current emphasis on the SAE *Sprachbund* by showing that there are potentially other areas in Europe that could pass as serious competitors. Haspelmath (2001: 1505–1506) acknowledges these possibilities, though with certain reservations. In the next section, with a view to elaborating on these issues, a few phenomena are scrutinized that either have been ignored completely or mentioned only in passing in the recent discussion within European areal linguistics.

More Isoglosses

The evidence adduced by Haspelmath is exclusively morphosyntactic; below, there is a variety of phonological issues that also display a clear geographical distribution. For the sake of brevity, another good candidate for areality in the realm of phonology, i.e., Sandhi, cannot be discussed here (Andersen, 1985). In addition, areal phenomena in Europe are approached from the perspective of grammaticalization theory by Heine and Kuteva (2005). The phonological sketches are complemented by others that focus on morphology. The list of features is again random, apart from the fact that they are not discussed in detail in Haspelmath (2001). When reference is made to more or less central languages or 'layers' of SAE, these judgements are based on Haspelmath's (2001: 1505) cluster map meant to represent the degrees of membership in the supposed linguistic area. The following (convenience) sample comprises 51 languages of all macrophyla represented in Europe (= Indo-European, Uralic, Altaic, Caucasian, Afroasiatic [= Maltese] and the isolate Basque). For the sake of simplicity, exclusively data from standard varieties are compared (occasionally allowing for a comparison of competing standards). In the east, the dividing line between Europe and Asia is assumed to run from the Arctic Sea southward along the Ural mountains to the Caspian Sea, then westward along the southern borders of Azerbaijan, Armenia, and Georgia to the Black Sea, where it follows the Turkish state boundary to the Mediterranean; in other words, the entire Trans-Caucasus and Anatolia are treated as integral parts of Europe. For the northern, western, and southern limits of Europe, a conventional solution has been taken.

Phonology

Rounded front vowels The first feature to be scrutinized is the presence or absence of vowel phonemes with the feature triple [¬low] + [front] + [round] =/y/, /Y/, /ø/, /œ/ as in French *culture*[kyltyʀ] 'culture' and *sœur* [sœʀ] 'sister.' The areal distribution of rounded front vowels is also partly discussed in Chambers and Trudgill (1980). Eighteen languages of the sample used here have two rounded front vowels, and one rounded front vowel is attested in two further languages, leaving a solid majority of 31 languages that lack vowel phonemes of this kind. Figure 1 reveals that there are two hotbeds in Europe where rounded front vowels occur.

These hotbeds are at a considerable distance from each other and are separated by a solid block of languages that do not have these vowels on their phoneme charts. Those languages that have rounded front vowels in the east belong to the Altaic macrophylum (more precisely, to the Turkic phylum), and thus this feature most probably has a genetic explanation. In the other hotbed, however, Indo–European languages of three different phyla (Germanic, Romance, and Celtic) and Uralic languages share the feature. However, not all members of the various phyla partake in this isogloss. French and the Puter (Lower Engadine) variety of Rhaeto–Romance are the only Romance languages to display rounded front vowels; the same holds for Breton among the Celtic languages. English, however, does not follow its Germanic relatives, all of which have rounded front vowels. Likewise, Saami and Mordvin, both lacking these phonemes, do not go along with their Uralic relatives. The group of languages that make do without rounded front vowels is genetically heterogeneous, too. Note, however, that the entire Slavic and Baltic branches are immune against rounded front vowels in a manner of speaking. Nevertheless, the isogloss cuts across genetic boundaries. The languages that share the feature are geographical neighbors: Those that have rounded front vowels are

Figure 1 Rounded front vowels [solid line = both /œ/ ∼ /ø/ and /ʏ/ ∼ /y/; dotted line = only /ʏ/ ∼ /y/]. ALB = Albanian, ARM = Armenian, ART = article, AZE = Azeri, BAS = Basque, BASH = Bashkir, BR = Bielarusian, BRET = Breton, BULG = Bulgarian, CAT = Catalan, CHUV = Chuvash, CZ = Czech, DAN = Danish, DU = Dutch, ENG = English, EST = Estonian, FAR = Faroese, FINN = Finnish, FR = French, FRIS = Frisian, GEN = genitive, GEORG = Georgian, GER = German, GR = Greek, HUNG = Hungarian, ICE = Icelandic, IR = Irish, IT = Italian, KURD = Kurdish, LAT = Latvian, LITH = Lithuanian, MAC = Macedonian, MALT = Maltese, MORD = Mordvin, NORW = Norwegian, OCC = Occitan, PERF = perfective, PL = plural, POL = Polish, PORT = Portuguese, RHAET = Rhaeto–Romance, RUM = Rumanian, RUSS = Russian, SAA = Saami, SAE = Standard Average European, SARD = Sardinian, SCG = Scots–Gaelic, SCR = Serbo–Croatian, SLOK = Slovak, SLOV = Slove-Slovenian, SP = Spanish, SW = Swedish, TAT = Tatar, TURK = Turkish, UKR = Ukrainian, W = Welsh.

spoken next to each other, and those that do not employ rounded front vowels are also in a neighborhood relation among each other. We do not encounter islands of either type interspersed among languages of the opposite type. However, there are two special cases, Albanian and Chuvash, which have /y/ as a phoneme but lack mid-high rounded front vowels and thus fail to partake in the larger isoglosses. Chuvash is renowned for its at times idiosyncratic behavior, as opposed to other members of the Turkic phylum. In the present case, Chuvash seems to mark the transition from the Turkic solution with two rounded front vowel phonemes to the situation found in the surrounding non-Turkic languages (Mordvin, Russian, etc.) where this class of phonemes is lacking, i.e., the absence of /ø/ is likely to be a product of language contact between Chuvash and its genetically unrelated neighbors. The complete absence of rounded front vowels in Mordvin has perhaps a similar explanation. Still, Chuvash is located next to the hotbed of rounded front vowels in the east containing the sister languages of Chuvash. Albanian, on the other hand, is cut off from the hotbed in the west by members of the Slavic phylum that do not allow for rounded front vowels at all. In all likelihood, Albanian is the remnant of an erstwhile more extended subarea to which, on earlier stages, Greek also belonged. Similarly, English and Welsh have lost rounded front vowels in the course of their history. For Breton, French, and Rhaeto–Romance, the feature is certainly a relatively late contact-induced acquisition: The two Romance languages have copied the feature from Germanic, and Breton developed it under French pressure. It is noteworthy that the *Charlemagne Sprachbund* is again involved, while other more central SAE languages are somewhat underepresented.

Quantity This section is concerned with the distribution of phonemic length in vowels (= /V:/), as in German *Hasen* [haːzən] 'hares' vs. *hassen* [ha(s)sən] 'to hate,' and consonants (= geminates /K_iK_i/), as in Italian *sanno* [sannɔ] 'they know' vs. *sano* [sa(ˑ)nɔ] 'healthy.' Ternes (1998) has studied both phenomena in a survey of the phonology of European languages that tacitly corrects a number of hypotheses put forward by Haarmann (1976a). Owing to the fact that, in a variety of languages, quantitative differences

Figure 2 Quantity correlation [solid line = phonemic V:; dotted line = phonemic K:].

epiphenomenally go along with more or less significant qualitative differences and are sometimes determined by the moraic prerequisites of the canonic syllable structure of a given language, it becomes difficult to decide whether length itself is the phonemically relevant factor. This and other aspects pose serious problems *inter alia* for the analysis of English and French. In the latter language, vowel length is marginally phonemic only in careful educated speech. In order to keep the discussion within reasonable limits, things are simplified by leaving problems of vowel quality and moraic templates aside. Moreover, cases like the French one are treated as instances of absence of a vowel quantity correlation.

Figure 2 surveys the presence and absence of phonemic long quantity for both vowels and consonants in Europe. Twenty-five sample languages (= slightly less than 50%) have distinctive vowel length, whereas only six display a quantity correlation for consonants. Four of these latter five distinguish quantities for both vowels and consonants. Were it not for Italian and Sardinian, one could be tempted to formulate an implication according to which phonemic quantity of consonants implies phonemic quantity of vowels. Long consonant phonemes are clearly a minority solution.

Independent of the fact that vowel length is distinctive in almost half of the present sample languages, the languages where this feature is attested display a clear areal bias. Discounting the isolated instance of distinctive vowel length in Maltese, one immediately notices that phonemic long vowels are a matter of a large area comprising the European northwest, Scandinavia, the Baltic region, and central and part of southwest Europe. Three Indo–European phyla in their entirety partake in the isogloss: all Celtic, Germanic, and Baltic languages distinguish short vowels from long vowels. This distinction is also found in varieties of Rhaeto–Romance and some members of the South Slavic and West Slavic subphyla, all of which border the territory occupied by Germanic languages. Of the Uralic languages, those that are spoken in the vicinity of Germanic, Baltic, or Slavic languages with length distinctions for vowels have the same feature, whereas Mordvin seems to lack it. Again, the feature cuts across major and minor genetic boundaries. The same is true of the group of languages that do not allow for phonemic quantity.

The areality of the phenomena under scrutiny cannot be denied. In contradistinction to the foregoing one, where it is possible to identify waves of spread and recession, much seems to speak in favor of a slow but continuous shrinking of the area characterized by phonemic length. Given the fact that, historically, all Indo-European languages employed distinctive vowel quantity, the present situation is suggestive of a large-scale loss of the feature in the successor languages of Latin, Ancient Greek, Old Church Slavonic, and so

on. Thus, the area from which phonemic length is absent has been expanding to the detriment of the hotbed of distinctive quantities. Interestingly, the two members of the *Charlemagne Sprachbund* are this time located on different sides of the dividing line: German is an uncontroversial case of a language with phonemic vowel length, and French does not form part of the isogloss (but see above). With the exception of Dutch, vowel length distinctions are not typical of other more central SAE languages.

Morphology

Morphological case distinctions European languages come in two varieties. One group has case inflections on nouns independent of the exact size of the paradigm (Finnish *talo* {house} 'house' vs. *talo-n* {house}-{GEN} 'of a/the house'), whereas the other group does not mark case on nouns by morphological means (cf. the Welsh 'construct state' *tŷ y dyn* {house} {ART} {man} 'the man's house'). For the present purpose, neither the genitive clitic of English and the mainland Scandinavian languages nor the facultative *s*-genitive on proper nouns in Dutch and Frisian are counted as instances of bound case morphology. The present sample languages distribute over the two possible types as follows: a minority of 20 languages lack nominal case inflections, as opposed to a majority of 31 languages that employ more or less sizable inventories of morphological cases on nouns. Figure 3 captures the areal pattern.

Nominal case morphology is largely a trait of languages located in the east and in the far west of the continent. A small strip extending from Norwegian in the north via French in the middle down to Maltese in the south is characterized by absence of morphological case distinctions on nouns. Outside this area, this feature is also shared by Kurdish in the southeasternmost corner of the map and the two Balkan Slavic languages Macedonian and Bulgarian, which are surrounded by full-blown case languages. Basque is the only case-inflecting island in largely caseless surroundings. As is the situation with the previous isoglosses, phyla are cut across. There are case-inflecting Celtic languages and caseless ones; the same applies to the Germanic phylum, where German and the insular North Germanic languages stand out as representatives of the case-inflecting type, whereas the remaining Germanic languages have lost the ability to inflect nouns for case. Rumanian is the only Romance language with nominal case-inflection, while Bulgarian and Macedonian are dropouts from the Slavic phylum, as they have given up their erstwhile fully functional case system. All Uralic and Altaic languages are case-inflecting, as are the Baltic languages, Armenian, Greek, Albanian, and the bulk of the Slavic phylum. Maltese is the only non-Indo-European language without nominal case inflection. The primary stronghold of case inflection is clearly the eastern part of the continent. In the northwest the feature seems to be on the decline in

Figure 3 Morphological case on nouns [solid line = languages without case inflection].

the Celtic languages, less so in Faroese and probably not yet in Icelandic.

In their older stages, the Indo-European languages (Old Irish, Old English, Latin, Old Church Slavonic, Old Persian, etc.) were all endowed with a nominal case paradigm that in its most conservative shape resembled closely the one of present-day Lithuanian. Therefore, the absence of nominal cases in many Romance, Celtic, Germanic, and some Slavic languages (and Kurdish, for that matter) is an innovation. Much the same can be said of Maltese in comparison to Classical Arabic. In the languages that currently inflect their nouns for case, this feature can be classified as a retention, a conservatism. Old French is reported to have employed a minimal bipartite case system during the earliest stages of documentation, while the nominal case system had already disintegrated in most of its sister languages outside the Balkans. The chronology of the disintegration of nominal case systems is suggestive of a spread of caselessness from the south northward, eventually cutting the formerly continuous area of case languages into two subareas. Presently, the isogloss separates the two members of the *Charlemagne Sprachbund* that again happen to be situated on different sides of the line. The absence of case inflection, however, unites many of the more central SAE languages (Dutch, Spanish, Portuguese, Sardinian, Italian).

Comitative-instrumental syncretism The next feature also belongs to the realm of case distinctions, although it is not restricted to bound morphology. The focus is on the grammaticalized expressions of comitative and instrumental relations independent of the morpheme status of their markers. The presentation is based on the findings of a long-term crosslinguistic research on the two categories, some of which are discussed in Stolz *et al.* (2003), Haspelmath (2001), and Heine and Kuteva (2005). Languages may belong to one of three classes: They use two distinct markers to encode comitative and instrumental separately (= asyncretic); they do not distinguish formally between the two categories (= syncretic); or they employ two markers, of which one exclusively encodes either comitative or instrumental and the other one covers both functions (= mixed). Europe stands out from the rest of the world, as it is the only continent where the syncretic type is statistically the strongest (everywhere else the asyncretic type dominates by far). Thirty-five of the European sample languages (= 69%) are syncretic, 11 are asyncretic, and five are mixed. Figure 4 suggests that the types are not randomly distributed over the continent but that there is a clear areal pattern.

The territory occupied by syncretic languages is divided into two subareas. The larger one covers most of the European north, west, and south. The smaller one is located in the extreme east; thus, the major homestead of the asyncretic type finds itself sandwiched between syncretic languages. What strikes the eye most is the fact that representatives of the mixed type never cluster anywhere. Where

Figure 4 Comitative–instrumental syncretism [solid line = syncretic; dotted line = asyncretic; dashed/dotted line = mixed].

they occur they are situated on the margins of the syncretic territory, often trapped between syncretic and asyncretic languages. This is indicative of a transition from one major type to the other. Not surprisingly, the isoglosses do not respect genetic principles. The Uralic macrophylum contains syncretic, asyncretic, and mixed languages. Slavic, Celtic, Baltic, and Germanic languages are distributed over two different types. These differences in class membership are not random but rather are areally motivated. Those languages that fail to behave like their next of kin converge with their next-door neighbors, either fully or partially.

Diachronically, the properties of the syncretic type seem to be innovations, at least in a number of the languages involved. It can be shown that the feature spread from Germanic to the Baltic languages and Estonian in the early days of their documented history and triggered their typological change from asyncretic to syncretic via mixed – which is the stage reached by contemporary Lithuanian. Germanic and Italo–Romance can also be held responsible for the present syncretic status of Slovenian, whereas Macedonian and Bulgarian conform to the general Balkanic picture that favors the syncretic type. A similar contact-based explanation is perhaps also possible for the mixed status of Hungarian (supported by German and Rumanian influence). In the east, syncretic properties have a genetic foundation, as all members of the Altaic phylum display the feature. Mordvin is again likely to have been influenced by the neighboring Turkic languages. Asyncretic languages are thus on the retreat.

Syncretism of comitative and instrumental is indeed a trait shared not only by the two members of the Charlemagne Sprachbund but also by those languages that belong to the more central 'layers' of SAE, including a variety of languages that do not partake regularly in isoglosses of the SAE languages.

Cardinal-based derivation of ordinals In Stolz and Veselinova (forthcoming), the relationship between ordinal numerals and cardinal numerals in terms of derivation is studied in a crosslinguistic perspective. There are various types, the major ones being:

1. no formal distinction (= unattested in Europe)
2. ordinals are regularly derived from cardinals, as in Tatar *běr* 'one' → *běr-ěncě* 'first,' *ikě* 'two' → *ikě-ncě* 'second,' etc.
3. FIRST is not based on ONE, all other ordinals follow pattern (b), as in Georgian *erti* 'one' vs. *p'irveli* 'first' as opposed to *ori* 'two' → *me-or-e* 'second,' *sami* 'three' → *me-sam-e* 'third,' etc.
4. FIRST and SECOND are not derived from ONE and TWO, respectively, all other ordinals follow pattern (b), cf. Swedish *en* 'one' vs. *första* 'first,' *två* 'two' vs. *andra* 'second' as opposed to *tre* 'three' → *tre-dja* 'third', *fyra* 'four' → *fjär-de* 'fourth,' etc.

On the basis of the data in Stolz (2001), Haspelmath (2001) considers the suppletive second ordinal, i.e., type (d) a potential SAE feature. Figure 5 reveals that this type is indeed the majority solution for the sample languages: 36 languages belong to type (d), 10 to type (c), and the remaining five are type (b) languages.

Type (d) occupies the large middle section on the map stretching from Saami in the north via Czech down to Sardinian in the south. The easternmost representative of this type is Mordvin, which, for once, does not show affinities to its Turkic neighbors. Irish marks the westernmost outpost of type (d) languages. The only region of Europe from which type (d) is completely missing is the southeast, where type (b) and type (c) dominate. Type (b) has a strong genetic foundation, as it is attested in all Altaic languages of the sample. The distribution of type (c) is less coherent because there are isolates and small subareas on the margins of the territories of the other two types. The largest of these comprises three West Germanic languages and Scots–Gaelic. Owing to the fact that other Celtic and Germanic languages are bona fide (d) type languages, it is clear that the isoglosses follow the familiar pattern or running criss-cross over genetic boundaries. Rumanian is the only representative of (c) type in the otherwise predominantly (d) type–oriented Romance phylum. Indo-European and non-Indo-European languages may form subareas together, as is the case for the (c) type languages Albanian and Maltese in the south and Armenian and Georgian in the southeast. The entire Uralic macrophylum partakes in the (d) type isogloss, together with the bulk of the Indo-European languages.

A word of caution is in order: There are areas of transition between the major and the minor types. Depending upon which variety of Frisian and Kurdish one chooses, the isoglosses may change direction: West Frisian follows Dutch and German (= [c] type), whereas North Frisian goes along with neighboring Danish (= [d] type). Zazaki Kurdish (Dimli) behaves like Georgian and Armenian (= [c] type), whereas other varieties of Kurdish join Turkish in the (d) type. In addition, French, with its contrast of *second* vs. *deuxième* 'second,' combines properties of both (c) type and (d) type and thus shares features not only with the bulk of typical SAE-languages that tend to belong to the (d) type but also with its partner in the *Charlemagne Sprachbund*, the (c) type language German. Turkish, Azeri, and Kurdish also allow for

Figure 5 Suppletive ordinals [dotted line = type (b); dashed/dotted line = type (c); solid line = type (d)].

two allmorphs of FIRST, one of that is suppletive (Turkish *bir* 'one' → *biri-nci* 'first' vs. *ilk* 'first'). These cases add to the areality of the phenomena under scrutiny, as they clearly demonstrate that neighborhood relations are crucial. The diachrony of the geolinguistic distribution patterns of the suppletive second ordinal still needs to be investigated more thoroughly. The most one can say for now is that German, Dutch, and Rumanian seem to have lost their erstwhile (d) type properties in the course of their history (for Rumanian, (d) type features may be found in certain stylistically marked registers).

Total reduplication Haspelmath (2001: 1503) observes that reduplication is practically unknown in contemporary European languages. This observation is correct as far as partial reduplication goes. The picture changes dramatically when we look at total reduplication, as studied in Stolz (2003). Total reduplication is firmly established as a morphological means in 25 of the sample languages, such as Maltese *ġew tnejn tnejn* {come.PERF.3PL} {two} {two} 'they came in pairs of two,' whereas the other 26 languages do not employ total reduplication in any systematic way. For a number of languages, the situation is difficult to assess. Figure 6 identifies the areal hotbeds of these types.

In Ibero–Romance languages, total reduplication is largely discouraged by normative grammar, although some patterns recur in the written register. This suggests that we are dealing again with an areal phenomenon. Those languages that disfavor total reduplication are located in the center of the map, almost completely surrounded by languages that have a predilection for total reduplication. Total reduplication is especially strong in the south and east as well as in the western rim of the continent.

As to genetic affiliation, a high percentage of languages where total reduplication is systematically employed belong to non-Indo-European macrophyla (12 out of 25 = 48% of the type). No non-Indo-European language is a bona fide case of a non-reduplicating language. Romance and Slavic phyla are divided into two, each with a substantial minority of the languages allowing for total reduplication. The entire Celtic phylum is reduplicating, whereas total reduplication is foreign to the Baltic and the Germanic phyla. Irrespective of these genetic preferences, Figure 6 shows that neighborhood relations are again decisive: Those Romance and Slavic languages that have total reduplication share this feature with their unrelated or only distantly related neighbors. In terms of the SAE *Sprachbund*, the southern half of it is cut off from the rest by this isogloss because Italian, Sardinian, and Albanian are reduplicating but French, German, and Dutch are not.

The isogloss of total reduplication continues far beyond the limits of Europe into Siberia, the Middle East, India and South Asia, and Africa. Those languages that do not participate in this isogloss, therefore, represent the marked case. As yet, nothing definitive can be said about the history of the

Figure 6 Total reduplication [solid line = reduplicating languages; dotted line = controversial cases].

isglosses. There is evidence for diffusion of total reduplication from the Levant westward in the Mediterranean. At the same time, avoidance of total reduplication seems to spread from central Europe to the southwest. The latter processes may be supported by normative grammarians, which leaves open the question of whether total reduplication is employed by native speakers in actual discourse.

Quintessence

Summing up what Figures 1 to 6 tell us, we observe that the distribution of the phenomena is not identical for any two isoglosses – in other words, isoglosses behave like individuals. This is of course the expected outcome. The individuality of the isoglosses notwithstanding, it is nevertheless possible to map the isoglosses onto each other to produce isopleths. Figure 7 depicts the clustering of isoglosses from the perspective of Russian as a kind of check for the SAE-centered approach of earlier contributions of the areal linguistics of Europe. Note that every sample language shares at least one feature with Russian.

Superficially, this cluster map suggests that, with the necessary changes, it is also possible to paint a picture of the geolinguistics of Europe with a language in the center of attention that is not a prime candidate for the status of SAE language. However, there is a relatively strong genetic component that determines similarity relations. Russian and its east Slavic sisters and neighbors, Bielarusian and Ukranian, share all six features. The next layer, with five shared features, is also exclusively Slavic, namely the west Slavic phylum plus Serbo–Croatian. Only on the third layer does genetic diversification set in: Here we find, in addition to Slovenian, the Baltic subphylum, Armenian, Greek, all varieties of Occitan, Basque, and Mordvin. The smaller the number of shared features, the higher the genetic heterogeneity of the layer. Interestingly, the languages with the minimal number of one single shared feature, Dutch, Frisian, and Breton, are all spoken in the west at a distance from Russian. Mainland Scandinavian languages and central Europe are likewise less prone to associate with Russian in isoglosses. Nevertheless, there seems to be a somewhat stronger westward orientation of the assumed area based on Russian, as the members of the Turkic phylum in the east display unexpectedly low degrees of similarity to Russian. Discounting the fact that the very first layers (with five or six shared features) on the cluster map are clearly grounded in the Slavic phylum, it is nevertheless possible to postulate an areal structure with decreasing numbers of shared features from center to periphery. Thus, this still very superficial look at Europe from the eastern vantage point supports the idea that there is a counterpoint to SAE. This view is in line with Lewy's ([1942] 1964) observation that there is an east–west asymmetry in Europe. As Haspelmath (2001: 1505) observes, the coexisting areas collide

Figure 7 Cluster map.

and overlap (most probably on the Balkans) and thus contribute to the geolinguistic diversity of Europe.

Europe as a Contact-Superposition Zone

From the above we learn that one and the same language may be part of residual and expansive areas, depending on the feature under review. What the data seem to suggest is the frequent diffusion of features originating on the (south)western mainland of the continent to the north and east. With a view to determining the balance or imbalance of SAE-based innovations and non-SAE-based ones, a much more detailed in-depth study of the geolinguistics of Europe is called for.

In the absence of such a study, one can tentatively conclude that:

- Europe is not a homogeneous linguistic area on a par with, say, the Balkan *Sprachbund*.
- The areal linguistics of Europe cannot be reduced to the identification of SAE features because:
- many languages of the continent are never or hardly ever included in the relevant isoglosses;
- many important features have not yet been checked for their areal distribution within the confines of Europe;
- the languages that fail to qualify as more central SAE languages (including those that do not share a single of the features characteristic of SAE) are likely candidates for at least one non-SAE linguistic area.
- The feature/isogloss-based approach to areal linguistics is methodologically superior to others, as it is based on proper linguistic criteria without the necessity of recourse to nonlinguistic ones.
- The feature/isogloss-orientation also gives us the opportunity to look beyond the geographic boundaries of Europe in order to establish whether the languages involved form part of a much larger macro area (Kuteva, 1998).

Given that isoglosses overlap and relatively seldom come in bundles, and given too that features may originate in different places, it is probably more accurate to speak of Europe as a contact-superposition zone (Koptjevskaja-Tamm and Wälchli, 2001) in lieu of using the suggestive label *Sprachbund* or even the somewhat less restrictive term 'linguistic area.' The present distribution of features on the European map is the product of a variety of processes that happened at different epochs. Not all of the phenomena can be attributed to the time of the Great Migrations or to any one major historical event of the

distant past (Haspelmath, 1998; Haspelmath, 2001: 1506–1507). Some innovations spread at a higher speed than others, some are attractive and are copied in language contact, others fail to meet this criterion and thus never extend beyond a certain region. One can therefore agree with Haspelmath (2001: 1507) when he concludes that the distribution of different features is 'due to different historical circumstances, and the correct picture is likely to be much more complicated than we can imagine at the moment.'

With a view to coming closer to the correct picture, future investigations on the basis of a much larger sample of languages will have to integrate both evidence from substandard varieties and diachronic data.

Writing as a Semiotic System

The alphabets of the Christian Orient that emerged from the Greek alphabet, like all writing systems, are to be conceptualized as semiotic systems – sets of interrelated signs of a special nature, forming a single integrated structure. As such, they consist of signs characterized by (a) expression, i.e., their shape, and (b) content, in this case an individual speech sound. Additionally, Saussure's notion of paradigmatics and syntagmatics should be transferred from the study of language to the study of writing. The paradigmatics of an alphabet refers to the standard order of its letters; the syntagmatics, to their sequence in a text.

To account for the origin and typology of alphabetic writing, represented by Classical Greek, one must refer to an analysis of Old Semitic (*see* **Asia, Ancient Southwest: Scripts, Epigraphic West Semitic**).

Old Semitic writing should be described as a consonantal–syllabic system of writing (rather than consonantal only, cf. Driver, 1948: 130, or syllabic only, cf. Gelb, 1963: 148ff.). The reason for this is that Old Semitic writing appears simultaneously as consonantal (paradigmatically, i.e., within the system) and as syllabic (syntagmatically, i.e., in the text). Typologically, this is a dual system, intermediate between consistently syllabic writing, i.e., syllabic both in paradigmatics and syntagmatics (e.g., Linear B, cf. **Aegean Scripts**), and alphabetic proper systems of writing (e.g., Classical Greek, cf. **Europe Alphabets, Ancient Classical**).

Origin of the Alphabetic Scripts of the Christian Orient

The Classical Greek writing system (**Table 1**) served as a prototype script, a writing model, for a group of Christian alphabets, namely Coptic, Gothic, Classical Armenian, Old Georgian, Caucasian Albanian, and Old Slavonic (as well as the Latin).

Writing as a Semiotic System

The alphabets of the Christian Orient that emerged from the Greek alphabet, like all writing systems, are to be conceptualized as semiotic systems – sets of interrelated signs of a special nature, forming a single integrated structure. As such, they consist of signs characterized by (a) expression, i.e., their shape, and (b) content, in this case an individual speech sound. Additionally, Saussure's notion of paradigmatics and syntagmatics should be transferred from the study of language to the study of writing. The paradigmatics of an alphabet refers to the standard order of its letters; the syntagmatics, to their sequence in a text.

To account for the origin and typology of alphabetic writing, represented by Classical Greek, one must refer to an analysis of Old Semitic (*see* **Asia, Ancient Southwest: Scripts, Epigraphic West Semitic**).

Old Semitic writing should be described as a consonantal–syllabic system of writing (rather than consonantal only, cf. Driver, 1948: 130, or syllabic only, cf. Gelb, 1963: 148ff.). The reason for this is that Old Semitic writing appears simultaneously as consonantal (paradigmatically, i.e., within the system) and as syllabic (syntagmatically, i.e., in the text). Typologically, this is a dual system, intermediate between consistently syllabic writing, i.e., syllabic both in paradigmatics and syntagmatics (e.g., Linear B, cf. **Aegean Scripts**), and alphabetic proper systems of writing (e.g., Classical Greek, cf. **Europe Alphabets, Ancient Classical**).

Origin of the Alphabetic Scripts of the Christian Orient

The Classical Greek writing system (Table 1) served as a prototype script, a writing model, for a group of Christian alphabets, namely Coptic, Gothic, Classical Armenian, Old Georgian, Caucasian Albanian, and Old Slavonic (as well as the Latin).

Table 1 Greek alphabetic writing

Coptic Alphabetic Writing

With the proclamation of Christianity as the national religion of Egypt, New Egyptian (Coptic) began to revive as the official state language, which since the time of Alexander the Great had been Greek. Christian culture in Egypt now began to develop on the basis of the local/national Coptic language, changing from the complex Demotic Egyptian script to a new writing system based on the Greek alphabet.

Coptic writing originated from a variant of Greek uncial writing that appeared in the first century B.C.E. The shapes of Coptic letters are essentially the same as the corresponding graphic symbols of Greek uncial writing. The earliest Coptic written documents are dated to the 2nd and 3rd centuries B.C.E.

To render corresponding Coptic sounds, 25 letters were borrowed from the Greek alphabet in the established sequence (Table 2). One of these, sixth in the sequence, is employed in Coptic only for its numerical value, reflecting the peculiarity of the Greek alphabet of a particular period when the Greek letter *stígma*, stemming from the archaic graphic symbol ϝ *dígamma*, was devoid of phonetic value, carrying only the numerical value of 6.

In the Coptic alphabet, the place of Greek ϙ *kóppa* is taken by the letter ϥ *fāj*, with the phonetic value [f] – specific to the later language. The letter preserves

Table 2 Coptic writing

Numerical values	*Phonetic values*	*Names*	*Coptic letters*	*Greek initial letters*

Table 3

Numerical values	*Phonetic values*	*Designations*	*Coptic letters*	*Demotic letters*	*Hieroglyphics*
–	š	šdj	ϣ	𐲝	𓈖
90	f	fāj	ϥ	𐲟	𓄡
–	ŋ	adj	ϧ	𐲢	𓄿
–	h	hŏri	ϩ	𐲤	𓎛
–	ğ	ğanğa	ϫ	𐲥	𓄡
–	(g. č) š)	šima	ϭ	𐲧	𓋴
–	tt	dīj	ϯ	𐲩	𓏏

the alphabetic sequence of the corresponding Greek prototype and has the numerical value 90.

The Coptic letter corresponding to the last symbol ϡ *sámpi* in the Greek alphabet is employed similarly to its Greek prototype, with its numerical value 900.

Table 3 presents the seven graphic symbols that complete the Coptic alphabetic sequence. The symbols are traceable to their corresponding demotic prototypes, expressing specifically Coptic sounds that have no phonetic equivalents in Greek. The names of the letters of the Coptic alphabet essentially reflect their corresponding Greek designations. In the properly Coptic part, the names of the letters are based on corresponding demotic designations.

The Coptic alphabetic sequence thus consists of two parts: a 'principal' part, corresponding to the Greek alphabetic sequence and repeating the phonetic and numerical values of Greek paradigmatics, and an 'additional' part, attached to Greek paradigmatics, with graphic symbols expressing specific Coptic sounds that have no phonetic equivalents in Greek. Thus, Greek paradigmatics – the phonetic and numerical values of corresponding graphic symbols – is fully preserved in that part of the Coptic alphabet that corresponds to the Greek alphabetic sequence.

Gothic Alphabetic Writing

The Gothic alphabet, created at approximately the same time, is similar (Table 4). In this case as well, the creation of a new alphabet was connected with the adoption of Christianity. In order to translate the Bible into Gothic, the bishop of the West Goths, Ulfilas (318–388 C.E.), rejected the ancient monumental Runic writing, linked to pagan beliefs, and invented a writing of a new type.

Greek uncial writing served as the model for the newly created Gothic alphabet, which is incontestably manifested in the shape of Gothic letters and essentially Greek alphabetic order, reflected in the paradigmatics of the Gothic alphabet.

In the Gothic alphabet, the paradigmatics of the Greek prototype is preserved by referring specifically Gothic phonetic units to those letters of the Greek phonetic series that have no sound value in Greek, or express sounds alien to the Gothic language. This prevents the violation of the paradigmatics of the prototype system. For example, the sixth place in the Gothic alphabetic series, with the numerical value 6, is held by the symbol 𐌠 with the phonetic value [q^w].

Eighth in the Gothic alphabet, instead of H *êta* we find a letter for /h/ (long vowels are alien to Gothic). Following it, with the numerical value 9 and replacing the aspirated stop Θ *thêta*, stands the letter 𐌸 designating the interdental spirant /θ/. Graphically, this letter is traceable to the Greek ψ *psî*, while the place corresponding to the Greek *psî* is occupied by the letter 𐌨 [h^w], numerical value 700 (the archaic Greek 𐌨 *thêta* served as the graphic prototype of this Gothic letter).

The place corresponding to the Greek Ξ *xî* in the Gothic alphabetic series is held by the letter 𐌾 with the phonetic value [j] (numerical value 60), believed to be a borrowing from the Latin.

The next letter Π in the Gothic alphabetic sequence, with the numerical value 70 (in place of the Greek O *ò mikrón*), expresses the phoneme /u/,

Table 4 Gothic writing

Numerical values	*Phonetic values*	*Gothic writing*	*Uncial Greek writing*	*Origin*
1	a	𐌰	Α	
2	b	𐌱	Β	
3	g	𐌲	Γ	
4	d	𐌳	Δ	
5	e	𐌴	Ε	
6	q	𐌵	Ϙ	Lat.
7	z	𐌶	Ζ	
8	h	𐌷	Η	
9	*þ*	𐌸	Ψ	
10	i	𐌹	Ι	
20	k	𐌺	Κ	
30	l	𐌻	Λ	
40	m	𐌼	Μ	
50	n	𐌽	Ν	
60	j	𐌾	Ϛ	Lat.
70	u	𐌿	Ο	Run.
80	p	𐍀	Π	
90	–	𐍁	Ϟ	
100	r	𐍂	Ρ	Lat.
200	s	𐍃	Σ	Lat.
300	t	𐍄	Τ	
400	w	𐍅	Υ	
500	f	𐍆	Φ	Lat.
600	χ	𐍇	Χ	
700	*hw*	𐍈	Θ	
800	*ō*	𐍉	Ω	Run.
900	–	𐍊	Ϡ	

traceable to a corresponding letter of Runic writing. To designate the value /u/, Ulfilas did not take the graphic equivalent of the Greek digraph OY but borrowed a letter from Runic writing. He did the same in designating the vowel /o/ by the letter 𐍉 that in the Gothic alphabetic series occupies the place of the Greek Ω *ô méga* (numerical value 800).

In the Gothic alphabet, the letter 𐍆 with the numerical value 90 derived from the Greek Ϙ *kóppa* is likewise here devoid of phonetic value.

Thus, in using the Greek alphabet as a prototype for the creation of Gothic writing, Ulfilas did not omit letters expressing specific Greek sounds from the alphabetic sequence but replaced them with letters with specific Gothic phonetic values. Thereby the paradigmatics of the Greek prototype system is reflected in Gothic, with the preservation of the numerical values of the respective letters in the Greek and Gothic systems.

The Greek and Gothic systems fully coincide. Unlike Coptic, the Gothic alphabet has no additional letters in comparison with the Greek alphabet.

Like Greek, the Coptic and Gothic alphabets contains 27 (i.e., 9 × 3) letters in all; of these, the first nine express integers, the following nine, tens, and the final nine, hundreds. The 27th Gothic letter – used only for the numerical value 900 – reflects the Greek episemon Ϡ *sámpi*, with the numerical value 900. The absence in Gothic of additional letters is accounted for by the fact that specific Gothic sounds were fitted into the framework of Greek paradigmatics.

Armenian Alphabetic Writing, *Erkat'agir*

Armenian historical tradition links the creation of the Armenian alphabet *Erkat'agir* or 'Iron writing' with the enlightened work of the first teacher of the Armenians, Mesrop Mashtots (d. 440).

The Greek basis of Classical Armenian writing (Table 5) is manifested primarily in the agreement of the alphabetic sequence with Greek paradigmatics, when letters expressing specifically Armenian sounds unknown to Greek are omitted. Some letters with specifically Greek phonetic values were omitted.

To create a new script, the compiler of the Armenian alphabet took the Greek writing system as a model. Each new letter was correlated with a Greek letter that expressed a corresponding sound in Armenian.

Classical Armenian, like Coptic, had more consonant phonemes than Greek. But the creator of Armenian writing had recourse to a different procedure from that used for Coptic. The additional letters of the Armenian alphabet were not placed at the end of the alphabetic sequence, but inserted at different places in the Greek paradigmatic sequence. This primary core of the Armenian alphabet, built on the basis of the Greek paradigmatics, commenced with the letter Ա *a* and ended with the symbol Ք *k'*.

Such a distribution of the additional letters of the Armenian alphabet among the letters of its primary core led to a total disruption of the system of numerical values characteristic of the Greek prototype. Agreement of numerical values in the Greek and Armenian systems is observable only between the first seven letters of the alphabet. Beginning with the eighth letter, the symbols of the Armenian system indicate different numerical values.

Since the Armenian system has a greater number of letters than the Greek prototype, it appeared practicable to create a fuller system of expressing numerical values in Armenian. By means of the $9 \times 4 = 36$ letters of Armenian writing, it proved feasible, with the aid of individual written symbols, to express thousands as well.

Moreover, Armenian breaks all graphic links with the letters of the Greek writing system. The Armenian letters that express sounds phonetically equivalent to Greek have nothing in common graphically with corresponding letters of Greek writing. This graphic peculiarity of *Erkat'agir* has provided ground for hypotheses on the origin of Classical Armenian writing from the most diverse written sources. The derivation of an entire writing system from a particular written source on the basis of similarities and differences in the shapes of individual letters, i.e., on the basis of a graphic analysis of the plane of expression is not methodologically justified. Graphic resemblance of individual letters in various writing systems is not sufficient for asserting their origin from one or another writing source. Such assertions require consideration of more substantive inner systemic characteristics of writing.

The paradigmatics of a writing system constitutes one such inner systemic characteristic of writing. In this respect, Armenian writing reveals an indubitable relationship with the Greek writing system. But the creator of Armenian writing consciously severed all external relations with the graphic symbols of the Greek prototype system, freely inventing the graphic form of corresponding letters according to a definite principle. In the course of such graphic creativity, Mesrop Mashtots could naturally consult the available graphic specimens from the most diverse writing systems, such as Aramaic–Pahlavi, Syriac, Ethiopic, Greek, etc., scripts whose writing displays some likeness to the graphic symbols of Armenian writing.

Armenian writing is the product of the ingenious creativity of its author rather than the result of the historical transformation or graphic reproduction of a definite writing. This accounts for the graphic links of Armenian writing with various systems. Such free creation of the graphic symbols of Armenian must have been motivated by a desire to conceal the dependence of the newly created writing on the Greek model. In this way, an apparently original national writing was created – seemingly independent of any external influences or links. The distribution of the additional letters of the Armenian alphabet among the symbols of the principal part, corresponding to Greek paradigmatics, can be explained by the same considerations. The sequence of symbols inherited from the Greek system was thereby violated, and a correspondingly new system of numerical values came into being.

In all probability, this was a manifestation of the tendencies in the eastern Christian cultural world of the period, dictated by specific religious and political considerations, toward concealing all links and dependence of the local Christian culture on Greek culture. (Similar tendencies were manifested in the creation of other scripts of the Christian period, particularly Old Georgian and Old Slavonic writing.)

Old Georgian '*Asomtavruli*' Writing

The derivation of the Old Georgian alphabet (early 5th century) from the Greek alphabet can be established on the basis of a number of inner structural indices of the Old Georgian writing system.

A noteworthy characteristic of the Georgian language throughout its history is the astonishing phonetic conservatism of the system. The phonetic structure of the Georgian language of the earliest period is preserved to the present day without significant phonetic changes. This largely accounts for the fact that Georgian writing fully preserves one-to-one correspondence between the phonetic units of the language and the graphic symbols of writing both in paradigmatics and syntagmatics (Table 6).

What writing system served as a model for the creator of the Old Georgian alphabet? There are two possibilities: Old Semitic writing or the Greek alphabet (or other alphabets deriving from it). In either case, one thing is clear in advance: a comparison of these systems with the sound units of the Georgian language shows that in Georgian a whole group of consonants would be identified, without phonetic equivalents in the systems juxtaposed. Thus, there were two groups of sounds in Georgian: the 'principal' sounds corresponding to sounds represented in the source script, and the 'additional' ones.

Clearly, the adoption of the Greek or Semitic writing system as the prototype would shape the principal and additional parts of the newly created

Table 6 Old Georgian writing

writing differently. Comparison from this point of view of the Semitic and Greek systems of writing with Georgian writing brings out a genetic relationship of the latter only with the Greek system and rules out its derivation from the Semitic writing system. The assumption of the Greek system as the prototype in the creation of the Old Georgian alphabet renders quite understandable the structure and character of the principal and additional parts of the Old Georgian alphabetic sequence. Only those sounds of Georgian that have no phonetic correspondence in Greek are found in the additional part.

Graphic analysis and comparison of Old Georgian letters with the corresponding Greek letters show their utter graphic incongruity and incompatibility. In the creation of Old Georgian writing, the Greek writing system was evidently taken as a model for identifying and distributing Georgian sound units, which were subsequently expressed by special graphic symbols. However, the graphic symbols of the Old Georgian alphabet do not repeat the Greek shapes, as in the Coptic or Gothic alphabets, or the Slavonic Cyrillic. On the other hand, a number of characters of Old Georgian writing manifest some graphic features that bring them close to the shapes of Classical Greek letters (and overlap with the shapes of Phoenician scripts). The Old Georgian characters ⴑ *ban* (cf. archaic Greek Β *bêta*), ⴒ *gan* (cf. archaic Greek Γ *gámma*), ⴓ *en* (cf. archaic Greek Ϝ *é psilón*), ⴔ *vin* (cf. archaic Greek Ϝ *dígamma*), etc. – all facing left – are the Old Georgian letters that come close to the archaic outlines of corresponding Greek letters. However, the majority of Old Georgian letters show no resemblance to the corresponding Greek letters. (The currently used shapes of Georgian letters, *Mxedruli*, represent centuries of paleographic development.)

How should one account for the graphic difference between the majority of Old Georgian letters and the paradigmatically corresponding characters of Greek writing, given the resemblance of some characters to their archaic Greek counterparts? Is this difference the result of natural development and graphic evolution of the Old Georgian system, during which it must have diverged considerably from the shapes of the characters of the archaic Greek prototype system that served as the basis of Georgian writing?

This assumption requires dating the formation of the Old Georgian alphabet on the Greek pattern to a very early period, when the archaic Greek writing system prevailed – directed from right to left, with letters slanting leftward, and with a number of archaic graphic and phonetic peculiarities. Even setting aside the difficulties on the cultural–historical plane that arise with such an assumption, the fact that a number of graphic and phonetic characteristics that emerged in Greek much later are reflected in the Old Georgian writing system renders such an assumption unlikely.

It should thus be assumed that the archaic Greek alphabet was used as the model for the Old Georgian, taking into account the graphic and phonetic changes that subsequently arose in the Greek system. The Old Georgian alphabet was therefore likely an artificial creation, the result of conscious archaizing and graphic stylization of the Classical Greek alphabet.

It appears feasible to analyze the graphemes of the Old Georgian monumental *Asomtavruli* writing as formed of a limited number of original graphic elements, the *straight line* and the *semicircle*. All the

The Caucasian Albanian writing

To the group of scripts of the Christian Orient should be added the still undeciphered writing of the Caucasian 'Albanians.'

The paradigmatics of the 'Albanian' writing counting 52 units is attested in an old Armenian manuscript, with the names of the signs rendered in Armenian letters (given in Table 7 in transliteration), which reflect the approximate phonetic values of the respective Albanian characters.

The paradigmatics of the Albanian script bears a certain resemblance to the Old Armenian, although we cannot make any conclusive judgment on the structure and provenience of the writing system in view of the absence of concrete texts in Albanian. A small number of inscriptions with Albanian characters awaits a definitive decipherment. Recent news of the recovery of long Christian Albanian texts on old Georgian palimpsests (which are as yet unpublished) makes us hope that the ultimate decipherment of Caucasian Albanian is a matter of time. According to preliminary reports, Caucasian Albanian is a language whose contemporary descendant should be seen in the North East Caucasian Udi language.

The Old Slavic Writing

Beginning in the 9th century A.D., fully developed original alphabets, based on the Greek alphabet, came into being in the Slavic cultural world. The Slavonic writing systems, called Glagolitic and Cyrillic, were invented for recording texts in the Old Church Slavonic language, in which divine worship began in the Slavic Christian world and the Slavic Christian literature was first written. Historical tradition ascribes this to the enlightenment activities of the Christian missionaries – the first teachers of the Slavs – the brothers Constantine, later surnamed Cyril (827–869) and Methodius (d. 885).

To all appearances, Glagolitic arose from 9th-century Greek minuscule writing. This manifests itself in the Greek arrangement of the Glagolitic alphabet – the paradigmatics of the letters essentially reflects the Greek sequence, broken only by the insertion of a number of letters expressing specifically Slavonic sounds.

This in turn caused some shift of the numerical values expressed by the letters. The number of Old Slavonic phonemes considerably exceeded the number of Greek phonemes, so it was necessary to create a whole group of additional characters for them. The number of letters in the newly developed writing, which was intended to simultaneously express the system of numerical values as well, could not be less than $9 \times 4 = 36$ (for the expression of integers, tens, hundreds, and thousands by individual letters). And indeed, the Old Slavonic Glagolitic originally contained $9 \times 4 = 36$ graphic symbols (Table 8).

The graphic individuality of Glagolitic writing stems from the fact that the letters of the Greek minuscule cursive are represented here in syntagmatics as isolated graphic symbols, but the symbols of the Glagolitic bear the imprint of their creator's graphic modification, formally distancing them from their Greek graphic prototypes. The ductus of the exceedingly complex and intricate letters of Glagolitic, with numerous flourishes and loops, is so peculiar that some researchers believe it to have been the result of Constantine-Cyril's independent original creativity.

There can be no doubt that the creator of Glagolitic deliberately modified and stylized the original Greek letters – perhaps with a view to concealing the dependence of the newly created writing on its Greek counterpart and to creating the impression of complete independence and originality.

Table 8 The Glagolitic alphabet

1	ⰰ	*a*	100	ⰿ	*r*
2	ⰱ	*b*	200	ⰾ	*s*

30	ⰼ	*h*	3000	ⰿ	*ə*
40	ⰽ	*k*	4000	ⰿ	*ȣ*
50	ⰾ	*l*	5000	ⰿ	*ä* (*ѣ*)
60	ⰿ	*m*	6000	ⰿ	*x*$_1$
70	ⱀ	*n*	7000	ⰿ	*ö*
80	ⱁ	*o*$_1$	8000	ⰿ	*ü*$_1$
90	ⱂ	*p*	9000	ⰿ	*N*

For a number of Glagolitic letters belonging to the additional part of the alphabetic series and lacking Greek graphic prototypes, the influence of some other, chiefly Oriental, sources may be hypothesized. Thus, for example, the Coptic characters ϣ *šāj*, ϫ *ǧanǧa*, and ϧ *ḫāj* may have served as prototypes of the Glagolitic letters ⰾⰾ *š*, ⰶ *ž*, and ⰽ *x*$_1$, and the Hebrew צ *ṣādē* for the Glagolitic ⱌ *c*, and so on.

The names of the letters of the Glagolitic alphabet were selected from Slavic words on the acrophonic principle, i.e., words whose initial phoneme coincided with the phonetic units expressed by the corresponding letters: *az*, *buki*, *glagol*, *dobro*, etc. Such assignment of letter names coincides with the naming pattern of Germanic runes and Gothic writing.

The second variety of Old Slavonic writing, known as Cyrillic, is clearer with respect to the source of the shapes (Table 9). Of the 43 letters of this alphabet, 24 repeat the graphic symbols of 9th–10th century Greek writing, with their respective phonetic values. Conforming with the Greek prototype, the combination of the letters OY served as the symbol for the vowel *u*. In comparison with the Greek prototype, the ligatures $i+a=$[ja], $i+e=$[je], and $i+o=$[ju] constitute graphic innovations.

Several letters designating specifically Old Slavonic sounds, i.e., *ž, c, č, š, št*, etc., appear to be borrowings with simplification from Glagolitic.

What is the relationship between the two varieties of Old Slavonic writing? According to the most widespread view, Constantine-Cyril must have invented the Glagolitic alphabet as an absolutely original Slavic writing, on the basis of the Greek prototype, borrowing at the same time a number of letters from various Oriental scripts. The extensive philological education and linguistic erudition of Constantine-Cyril – a philosopher and first teacher of the Slavs – render understandable the links displayed by Glagolitic with Greek and a number of oriental scripts.

Table 9 The old Slavic scripts

The graphically complex and intricate Glagolitic writing, invented by Constantine-Cyril, is second to

the graphically more perfect variety of Old Slavonic writing – the so-called Cyrillic – with its geometrically simple form of letters based on Greek uncial writing. This second variety of Old Slavonic writing, with certain systems and graphic modifications, is represented in particular by the modern Russian alphabet. This emerged after simplifications in 1708–1710 under Tsar Peter the Great, which eliminated ѡ ѧ ѧ ѱ ѯ, and after the Revolution in 1917, which eliminated ѕ ѕ і ѯ ѳ ѹ Ѹ ѵ ѣ.

A Typology of Invention of Ancient Alphabetic Writing Systems

A comparative study of various ancient alphabets reconstructs the typology of writing, yielding a general picture of the invention of alphabetic scripts based on a sample writing system that served as a model for the newly created systems.

The first and principal stage of this process is the breakdown of the phonetic side of a language into separate phonetic units to be expressed in writing by special graphic symbols, in essence the creation of the 'plane of content' of the writing system. This basic stage of the creation of writing essentially constitutes a phonetic–phonemic analysis of language for which a writing is being created. This is conducted on the basis of a comparison of the phonetic aspect of the language with the sound units represented in a definite sequence in the writing system it takes as a model.

The isolation and ordering of the phonetic units of a language for which a script is being created presupposes the simultaneous invention of specific graphic symbols by means of which these sounds will be expressed. Essentially this is the creation of the 'plane of expression' of the writing system. These two processes – the isolation and arrangement of the phonetic units of a language in a definite sequence and the invention of graphic symbols to express them – are interrelated procedures, presupposing each other. The shaping of both the plane of content and the plane of expression of a writing system is a single creative process of the inventor.

Exact reproduction of the outlines of corresponding graphic symbols of the prototype system, arranged in a definite sequence, would be the simplest and most natural way of shaping the plane of expression of the newly created writing system. Additional letters, expressing sounds specific to the given language, might be borrowed from other writing systems possessing similar sounds, or be created by modifying letters of the given system.

From the viewpoint of the plane of expression of a system, the Coptic, Gothic, and Old Slavonic (Cyrillic) alphabets are of similar character, all being based on Greek writing, not only with respect to the inner structure, but also to the shape of the corresponding Greek uncials.

A completely different way of shaping the plane of expression of a script is presented when the graphic symbols of the prototype system are transferred to the newly created system not in the same graphic form but with certain (possibly considerable) graphic modifications. This method alters – often beyond recognition – the original shape of the initial letters of the system (cf. the shapes of the Glagolitic letters in juxtaposition with Greek minuscule writing). Such graphic modification of the model may have been effected consciously, in order to conceal the dependence and connections of the newly created script with the system of the prototype writing.

Armenian *Erkat'agir* represents an extreme expression of this tendency, for the plane of expression of the Greek prototype is fully replaced. The graphic symbols of *Erkat'agir* were largely invented independently of Greek writing as the result of the creativity of its inventor, making use of various non-Greek graphic specimens.

In this respect, Armenian writing is typologically opposed to Coptic, Gothic, and Cyrillic; they represent extreme poles. Between them may perhaps be placed Glagolitic. It does not graphically break completely with the Greek system, but its letters are highly modified and graphically stylized. Old Georgian *Asomtavruli* belongs to the same typological group deriving from the Greek prototype.

The entire paradigmatic series of the Greek system is fully reflected in the Old Georgian alphabet, as well as in Coptic and Gothic; all $9 \times 3 = 27$ letters of the Greek prototype have been taken over into these alphabets in the same sequence, with corresponding phonetic and numerical values. Greek 'episemons' are transferred in the same function (i.e., only as symbols expressing definite numerical values; cf. the Coptic letters with the values 6 and 900, and the Gothic letters with the numerical values 90 and 900), or they acquire in the new systems specific phonetic values characteristic of the given language.

The paradigmatics of the initial writing system is essentially preserved through phonetic substitution and retention at relevant places in the alphabetic series of the newly created writing of all the graphic symbols of the prototype system. The paradigmatics of the prototype system is thereby mapped, as it were, onto the alphabetic series of the newly developed writing.

In Gothic, such mapping of the paradigmatics of the Greek prototype system onto the alphabetic series was effected without the addition of any characters

with specifically Gothic phonetic values; these values are fully accommodated in the paradigmatics of the Greek prototype. In Coptic and Old Georgian, there remained a certain number of sound units that had to be expressed in writing. These specific sounds and the graphic symbols designating them were added to the principal part of the alphabetic series by way of completing it, reflecting the paradigmatics of the initial prototype system with $9 \times 3 = 27$ graphic symbols. Such additional characters permitted the expression of numerical values of thousands in the Old Georgian alphabet as well.

The Armenian alphabet is based on an essentially different paradigmatic principle, typologically opposing it to the Coptic, Gothic, and Old Georgian writing systems. In drawing up the Armenian alphabet, all the episemons were removed, as well as all the letters designating sounds specific to Greek but not characteristic of Armenian. It appears that drawing up the Armenian alphabet did not involve substitution of Armenian sounds for the Greek phonetic values, but a reduction of the Greek alphabetic series to a sequence containing only correlates of Armenian sound units that had to be expressed by special letters. The Greek paradigmatic sequence originating in this way served as the initial nucleus of phonetic values on the basis of which the entire system of the Armenian alphabet was shaped by adding specifically Armenian sounds via specific letters.

However, these specifically Armenian values do not constitute a continuation in the alphabetic series of the principal part, but the symbols of the additional part are inserted at various places between the graphic symbols of the principal part, thus upsetting the original paradigmatics motivated by the Greek prototype, and accordingly the system of numerical values characteristic of the initial Greek model.

Old Georgian and Glagolitic share the principle of distancing the graphics of the new alphabet from that of the prototype system. This was done to characterize the emergent system as an independent national writing with no outward resemblance to other contemporary writing systems.

Classical Armenian writing, with its graphics totally differing from the Greek prototype, created by Mesrop Mashtots, proved an extreme manifestation of this principle. Fully basing himself on the Greek alphabet in inventing the Armenian alphabet, Mashtots totally changed the graphics of the prototype system. In this way, all external links with the Greek prototype are severed and a semblance of the complete independence and originality of the newly created writing is created.

The inventor of the Old Georgian alphabet deliberately modifies the Greek prototype system, for the same purpose. In the new system, the inventor does not break totally with the Greek graphics, but transforms it by a deliberate archaization of certain signs of the prototype system. In the newly created system, the inventor does not break totally with the Greek graphics, but transforms it by a deliberate archaization of certain signs of the prototype system and by graphic modification of corresponding characters. In this way, the creator of the Old Georgian alphabet achieves essentially the same result in inventing an original national writing.

Such tendencies in the Eastern Christian Cultural World – dictated by political and religious considerations – led to the creation of several outwardly differing writing systems, resting on Greek writing but exhibiting outward graphic independence with respect to the Greek prototype system.

In many originally alphabetic writing systems, created for the exact expression of the phonetic side of a language, the spelling of words may no longer fully reflect their actual pronunciation, owing to more or less significant transformations of the phonetic system. The sound syntagmatics of the language may become ever more removed from the graphic syntagmatics that reflected the phonetic make-up of respective words at the time of the creation of the alphabet and at early stages of its development.

In such later alphabetic systems, the graphic structure of individual words essentially represents a conventional sign for expressing their phonetic side. In such systems, individual graphic symbols may emerge, in syntagmatics, not as representatives of separate sounds and phonemes, but as graphic elements of a certain syntagmatic aggregate expressing the phonetic aspect of a whole word (cf., for instance, the spellings of individual words in modern English or French).

A logical sequel to such a disparity in the development of the phonetic aspect of a language and the ancient syntagmatics of writing may be the transformation of a writing of alphabetic origin into a quasilogographic system with individual letters or syntagmatic groups of letters expressing whole words (at a total disparity between the phonetic values of these letters and sounds that form these words). The writing breaks, as it were, all links with the phonetic side of the language, turning into a system independent of language, with a definite number of graphic symbols and special rules reflecting the ancient phonetic syntagmatics. It is only in this sense that one can speak of the 'autonomic' character of writing.

Evaluation in Text

Evaluation in Context

Evaluation is one approach to an area of interest in the analysis of discourse that focuses on attitudes of speakers or writers toward what they are saying or toward their interactants. Other approaches to the same broad area of interest include stance, appraisal, modality, and metadiscourse. This diversity of terminology reflects not so much defined theoretical oppositions as the outcome of attempts to map a complex area from different starting points.

In fact, the term evaluation is commonly used to refer to four related but distinct concepts: (1) a set of language resources (often, refer to as evaluative language), (2) a set of meanings realized through language, (3) the function of part of a text, and (4) an activity carried out by the writer or speaker through language. Similarly, stance is sometimes used to refer to a set of resources (e.g., stance adverbials) or a set of meanings (e.g., stance-taking when used for writer/speaker activity). The terms appraisal and modality refer to systems of meanings. Metadiscourse is used to refer to a subset of the language items usually identified as evaluative.

The concepts of evaluation as a set of meanings and as a set of resources are very closely related; a meaning is identified through the language resources used, and those language resources are said to be evaluative because of their meaning. Which meanings can be categorized as evaluative is a further area of debate. Common definitions focus on the notion of valuation – 'good' versus 'bad' – and of subjectivity or intersubjectivity. Some terms, such as appraisal and metadiscourse, are restricted to some of those meanings only; others, such as stance, tend to be more inclusive. At the most explicit end of the valuation cline, language items such as *excellent* or *disaster* realize and identify meanings of 'good' and 'bad.' The expression of 'good' and 'bad' may be less overt than in these items, however. Phrases such as *par for the course* (Channell, 2000) or *in the middle of* (Stubbs, 2004) can be shown to be intertextually evaluative, in the sense that there is evidence that their typical use is in the context of negative evaluation. (*Par for the course* usually indicates that an undesirable event is typical, as in *Sloppy research is par for the course in this [TV] series*. Even less intuitively obvious is *in the middle of*, whose most typical context is in phrases such as *in the middle of the night*, which usually indicate an undesirable event, as in *Once he had to call out a doctor in the middle of the night*.) Louw (1993, 1997) notes that such implicit meaning can be indicative of an unstated ideology and that the effect of some literary texts can be explained in terms of the highly covert presence of such meanings. In addition, evaluation can be expressed through the grounds or evidence for evaluation (evoked appraisal as opposed to inscribed appraisal in the terms used in Martin, 2000), as with a

Evaluation in Text

Evaluation in Context

Evaluation is one approach to an area of interest in the analysis of discourse that focuses on attitudes of speakers or writers toward what they are saying or toward their interactants. Other approaches to the same broad area of interest include stance, appraisal, modality, and metadiscourse. This diversity of terminology reflects not so much defined theoretical oppositions as the outcome of attempts to map a complex area from different starting points.

In fact, the term evaluation is commonly used to refer to four related but distinct concepts: (1) a set of language resources (often, refer to as evaluative language), (2) a set of meanings realized through language, (3) the function of part of a text, and (4) an activity carried out by the writer or speaker through language. Similarly, stance is sometimes used to refer to a set of resources (e.g., stance adverbials) or a set of meanings (e.g., stance-taking when used for writer/speaker activity). The terms appraisal and modality refer to systems of meanings. Metadiscourse is used to refer to a subset of the language items usually identified as evaluative.

The concepts of evaluation as a set of meanings and as a set of resources are very closely related; a meaning is identified through the language resources used, and those language resources are said to be evaluative because of their meaning. Which meanings can be categorized as evaluative is a further area of debate. Common definitions focus on the notion of valuation – 'good' versus 'bad' – and of subjectivity or intersubjectivity. Some terms, such as appraisal and metadiscourse, are restricted to some of those meanings only; others, such as stance, tend to be more inclusive. At the most explicit end of the valuation cline, language items such as *excellent* or *disaster* realize and identify meanings of 'good' and 'bad.' The expression of 'good' and 'bad' may be less overt than in these items, however. Phrases such as *par for the course* (Channell, 2000) or *in the middle of* (Stubbs, 2004) can be shown to be intertextually evaluative, in the sense that there is evidence that their typical use is in the context of negative evaluation. (*Par for the course* usually indicates that an undesirable event is typical, as in *Sloppy research is par for the course in this [TV] series*. Even less intuitively obvious is *in the middle of*, whose most typical context is in phrases such as *in the middle of the night*, which usually indicate an undesirable event, as in *Once he had to call out a doctor in the middle of the night*.) Louw (1993, 1997) notes that such implicit meaning can be indicative of an unstated ideology and that the effect of some literary texts can be explained in terms of the highly covert presence of such meanings. In addition, evaluation can be expressed through the grounds or evidence for evaluation (evoked appraisal as opposed to inscribed appraisal in the terms used in Martin, 2000), as with a

comment such as *It rained all day*, which might be evidence for positive evaluation (farmers in a dry country) or negative (holiday-makers in a typically damp one). Some comparative language items, such as *only* or *nearly*, frequently indicate the most likely interpretation of evoked evaluation; compare *It took us under three hours* (good) and *It took us nearly three hours* (bad). Defining evaluation as subjectivity allows other assessments, such as likelihood or importance, to be included in the concept, whereas defining it as intersubjectivity suggests that items appealing to the interaction between the speaker/writer and hearer/reader should also be included.

Similarly related are the concepts of evaluation as a set of resources or meanings and evaluation as the function of a specific part of a discourse; the function is often recognized by the presence of particular items. Labov (1972) and more recent writers (e.g., Eggins and Slade, 1997) propose that evaluation is one element in narrative structure, with the function both of delaying the action and so creating suspense and of indicating to the hearer what the point of the narrative is. Winter (1982: 9) suggests that one of the most basic relationships between clauses in a discourse is that of situation-evaluation; in other words, a text producer first gives information and then assesses it. Hoey (1983, 2001) elaborates this as a basis for exploring the organization of text. He describes a number of culturally popular text patterns (such as Situation-Problem-Response; or Situation-Goal-Response), each of which ends with an evaluation element that indicates the writer's assessment of the success of the enterprise described in the preceding text. The Evaluation section is marked either by evaluative lexis (such as *success*) or simply by the position of the section and its relation to the information in the rest of the text. In fact, however, Hoey emphasizes that, although the term evaluation may be used to label one part of the pattern, every element of the pattern relies on evaluation (the Problem is 'that aspect of the situation that is evaluated as problematic' and so on). In other words, the writer's attitude toward the material is what structures the text as a whole. The self-reflective and interactive nature of the Evaluation segment is emphasized by Sinclair (1988), who proposes that any written text is composed of a hierarchy of moves, the final one at each level being interpretable as a reflection on the previous ones, similar to the follow-up element in spoken exchanges that confirms the satisfactory completion of the exchange.

Finally, the notion of evaluation as a function or activity is articulated by Hunston (1989, 1994), who proposes a model of evaluation that reacts to a number of elements in Winter's, Hoey's, and Sinclair's work. First, there is a clear interdependence between Situation and Evaluation, that is, between **what** is evaluated and **how** it is evaluated. In other words, the writer's assessment or point of view is visible in the articulation of both these elements. More exactly, the distinction is not between a thing and the evaluation of the thing but between a thing evaluated as a particular kind of entity and a quality ascribed to that entity. In Hunston's work, these are described as the status and value functions of evaluation. Second, evaluation, particularly in its value function, is not necessarily realized as a set of discrete items but is pervasive, cumulative, and perhaps implicit. Third, evaluation as an element in text structure has an organizing function. Although evaluation may not be restricted to the third move in a sequence, that move does have a self-reflective function, labeled relevance by Hunston.

Researchers into the broad area covered by evaluation face two main problems – the first practical, the second theoretical. The first is that evaluation, whether it is conceptualized as a set of meanings or as a set of functions, is recognized by language items (words, phrases, and so on) that are identified as evaluative. The identification of such items is essential if a reading of the evaluative meanings of a text is not to be subjective to the point of idiosyncrasy. Yet evaluative items are not a closed set; evaluation, as previously noted, may be implicit (evoked) or cumulative; and there is no one-to-one relation between an item and its evaluative meaning in all contexts (Silver, 2003). The quantification of apparently evaluative items (e.g., Hyland, 1998; Conrad and Biber, 2000) is necessary when comparing large amounts of text, but such approaches sit uneasily with the highly interpretative analysis of a single text. The problem of reconciling large-scale and small-scale methods of analysis has not yet been solved.

The theoretical question is where to locate evaluation within a theory of language. Put simply: What kind of thing is evaluation (a meaning, a function, a set of items)?; what is nonevaluation and how is it recognized?; and how should the various aspects of evaluation (good-bad, certainty, interactivity, and so on) be seen to relate to one another? Martin (2000) and White (2002), working within the systemic-functional tradition, provide the clearest answers to these questions, identifying evaluation or stance as belonging to the interpersonal metafunction, thereby opposing it to the ideational and textual metafunctions, and proposing a set of systems to account for the various types of meaning. Similarly, reserving the term evaluation for part of a text allows it to be differentiated clearly from other parts. Other writers avoid the problem either by limiting the scope of the

phenomena they work on (e.g., Conrad and Biber's study of stance adverbials) or by focusing on the multifunctionality of evaluation or stance or of metadiscourse itself (e.g., Hunston and Hyland) and ignoring what lies outside.

The Polypragmatic Nature of Evaluation

One interpretation of the functionality of evaluation has already been mentioned. Thompson and Hunston (2000) further interpret the functions of evaluation as (1) to construe cultural values and the relationship between the entities in the text and those values, (2) to construe a relationship between writer and reader, and (3) to organize the text. Any piece of evaluative language is polypragmatic in that it may perform two or three of these functions simultaneously. As an illustration, here are extracts from an opinion article discussing the electoral prospects of the right-wing UK party the British National Party (BNP) (Hugh Muir, 'We can halt the far right's rise in London and the north,' *The Guardian* 14 May 2004). We have numbered the sentences for ease of discussion and underlined the instances of evaluation that are discussed.

> (1) <u>It is not hard to see</u> why the <u>racist</u> party <u>craves</u> a London assembly seat. (2) Unlike local councillors, assembly members elected from party lists have the right to claim a mandate from the whole of London. (3) They have the benefits of office, the resources, the staffing and the media recognition. (4) Mr Douglas and his party—which in its senior ranks includes <u>convicted thugs, football hooligans, vandals, police bashers, gay bashers and fraudsters</u>—will be in a position to influence key committees. (5) He could use his own experience to help the Metropolitan police authority, with football hooligan convictions going back 14 years. . . .
>
> (6) Searchlight, the anti-fascist organisation, has a national Stop The BNP campaign. . . . (7) But what is also needed to stop a national <u>disaster</u> in London is a <u>determined push</u> by all the mainstream parties. . . . (8) <u>It could be argued that</u> the BNP would never win a seat if the main parties spent less time <u>plotting</u> and writing <u>platitudes</u> to local papers, and more working the streets and getting core supporters into the polling booths. (9) Today in London, Labour begins a leafleting campaign and Mr Livingstone will be visiting mosques. (10) <u>It is a start.</u>
>
> (11) That said, the parties cannot do it all. (12) If we vote for anyone but the BNP, it will increase the turnout and <u>make it far more difficult</u> for the <u>racists</u> to reach the required threshold. (13) Minority communities are entitled to look to the mainstream parties to stop the BNP. (14) But until there is some indication that these parties care about this as much as we do, <u>we may be advised</u> to look to ourselves.

The first function of the evaluation in this text is to tell the reader the writer's opinion about how entities expressed in the text, such as the BNP, relate to a given system of cultural values. In doing so, it both reflects and construes those values. In the text, members of the BNP are described as *racists* (1, 12) and as *thugs*, *hooligans*, *vandals*, and *fraudsters* (4). The verb *crave*, indicating a desire that is irrational and out of control, is used to describe the BNP's ambitions (1). The possible success of the party in elections is referred to as a *disaster* (7), which should be countered by a *determined push* – a phrase that is used almost exclusively in the context of positive evaluation of the goal of the pushing. The other, mainstream parties are criticized more mildly, with their activities described as *plotting* and *platitudes* (8) and as detracting from the more important goal of preventing the BNP from obtaining seats. These evaluative items, and others, which propagate (Lemke, 1998) through the text, indicate that the writer strongly disapproves of the BNP and, moreover, that the writer presupposes that his readers will share this disapproval.

The second function of evaluation, to construe a relationship between the writer and reader of the text, is achieved partly by the assumed sharing of values – the reader is in a sense complimented by the assumption that dislike of the BNP is shared. In addition, phrases that indicate a shared experience, such as *it is not hard to see* (1), or shared ambition, such as *make it far more difficult* (12), construe solidarity and consensus. Furthermore, what is sometimes referred to as hedging in phrases such as *it could be argued that* (8) and *we may be advised to* (14) mitigates assertions and directives for which common ground is not assumed and thus construes a deference toward and respect of the reader's views.

Finally, evaluation serves to organize the text. Arguably, this extract is composed of three sections, each a paragraph. They may be described as (1) Statement of Problem, (2) Recommended Response A (action by political parties), and (3) Recommended Response B (action by individuals). Thus, the text as a whole is designed to present an evaluation and a reaction to that evaluation. In addition, each of the three units has what might be called an evaluative structure. Unit 1 (1–5) begins with a statement of opinion (*it is not hard to see why*) that prospects (the term used by Sinclair, 1993) the rest of the paragraph as providing supporting evidence. Less directly, the rest of the paragraph can be seen as partly serving to justify the negative evaluations in *racist* and *craves*. Unit 2 (6–10) consists of a concession (Searchlight is carrying out some positive actions) followed by a counterassertion (political parties also need to be involved). It is concluded by an assessment that summarizes and evaluates what has gone before (*it is a start*, 10) and so completes the unit. The final unit

(11–14) begins with an encapsulation (the term used by Sinclair, 1993) of the preceding unit (*that said*) and a prospection (*the parties cannot do it all*) predicting further recommendations. A specific recommendation follows – *vote for anyone but the BNP* – together with an explanation of why this is a good idea, culminating in the general exhortation to *look to ourselves*.

Value, Assessment, and Appraisal

Of the three main functions of evaluation previously mentioned, it is the first that has traditionally received most attention within linguistics: the expression of the speaker's attitude toward entities and propositions. The majority of earlier studies worked with the fundamental but relatively nondelicate distinction between positive and negative evaluation. The focus was frequently on lexical items, and a central issue was the identification of precise nuances of connotative meaning of individual items (see e.g., Cruse, 1986). Different scales of values were referred to (good/bad, desirable/undesirable, important/unimportant, etc.) but typically in a nonsystematized way. However, over the past 20 years, there has been an increasingly sophisticated attempt to describe the range of values that are drawn on in the process of evaluation, to relate these to the kinds of entities that are evaluated, and to apply the resulting description in the analysis of evaluation in discourse.

One area in which these issues first came to the fore was the analysis of academic writing. Hunston (1989, 1994) explores the ways in which research is evaluated, focusing primarily on the notions of goal-achievement and of fit. Research methods and results are evaluated positively by being shown as achieving the researcher's, or the research community's, goals. Research results and interpretations are evaluated positively by being shown to fit into a network of knowledge, theories, and hypotheses. For example, in the next extract (from Pubmedcentral), the data mentioned in sentences (2) and (3), and by implication the whole experimental process, are given positive value because they successfully achieve the aim stated in sentence (1): *to test whether the . . . cells . . . are actually contributing*. However, the hypothesis contained in sentence (1) (*genetically modified cells in the GM-CFU population contribute to the posttransplant repopulation of peripheral book and marrow hematopoietic cells*) is given a negative value in sentence (3) because there is no positive fit between the hypothesis and the experimental results.

> (1) To resolve this question, we decided to analyze the data derived from an ongoing MDR-1 chemoprotection trial for advanced breast and ovarian cancer patients to test whether the genetically modified cells in the GM-CFU population are actually contributing to the post-transplant repopulation of peripheral blood and marrow hematopoietic cells. . . . (2) The data from this study showed that the frequency of transduction (as measured by a GM-CFU plating assay in taxol) immediately post-transduction was the same in the suspension and stromal transduction protocols. . . . (3) These data suggest that the GM-CFU cells from the suspension method are not contributing to the hematopoietic recovery immediately posttransplantation. . . .

Thetela (1997) further discriminates within the values identified by Hunston, arguing that they can be grouped into a four-cell grid, as in Table 1. The grid represents the intersections of the evaluated entities (columns) and the value ascribed to the entities (rows).

In the Pubmedcentral extract, the negative evaluation of the hypothesis contained in sentence (1) falls into the category significance. There are several indications of degrees of certainty: *show* (2) evaluates the findings of the data as certain and *suggest* (3) lowers the degree of certainty with which the interpretation of the findings is advanced (for an alternative approach to handling these values see later discussion). The overall aim of the article is to contribute to usefulness by establishing the effectiveness of certain methodological procedures (the final sentence of the extract explicitly evaluates the study as useful for other researchers).

The most fully developed current model of values in discourse is Appraisal theory, developed by Martin and his associates within a Systemic Functional Linguistics framework (see Martin, 2000; Martin and Rose, 2003; White, 2002; Macken-Horarik and Martin, 2003; cf. Lemke, 1998, for an alternative account of evaluation within the same framework). The Appraisal model was originally developed to handle the analysis of evaluative meanings in textbooks, but it has been expanded to become a tool for mapping the values through which a culture makes sense of its experiences. The three major categories established in the model can be illustrated by the following short extract from an advertisement for an American beach resort (from Brignatinebeachnj.com).

Table 1 Parameters of evaluation in research articles

	Process/methods	Product/ findings/ knowledge
Worthiness (validity)	Usefulness	Significance
Fixedness (reliability)	Control	Certainty

Source: Adapted from Thetela (1997: 114, Table 4). Reprinted with permission from Elsevier.

(1) Brigantine Beach … an island you'll love for life! (2) South Jersey's best kept secret—Brigantine Beach—is a beautiful, pristine hideaway for families seeking a safe, peaceful haven. (3) Our community is naturally friendly. (4) Cultural events and recreational activities provide the opportunity to enjoy quality time with family friends and visitors. (5) If it's night life that interests you, Brigantine Beach is just minutes away from Atlantic City's endless casino excitement and world famous boardwalk.

The core resource for the realization of appraisal is Affect, as exemplified in (1): *you'll love [Brigantine Beach] for life*. Affect is the most congruent expression of appraisal because it construes evaluation in terms of the appraiser experiencing a reaction (in this case, love) directed toward, or stimulated by, the appraised entity. Affect can be seen as 'institutionalized' (in Martin's phrase) into two other major categories, in which the affectual reaction is, as it were, externalized and construed as a quality of the appraised entity. Whereas Affect may be directed toward any kind of entity, the two other categories are distinguished according to the kind of entity appraised and the kind of values drawn on. Appreciation involves aesthetic assessments of 'products, performances and naturally occurring phenomena' (Martin, 2000: 159). A typical example occurs in (2), where Appreciation is drawn on in describing the beach as a *beautiful, pristine hideaway*. Judgment, on the other hand, has to do with ethical assessments of human behavior; sentence (3) expresses a judgment of the community as *naturally friendly*. This two-way division is justified not only on the grounds that, as humans, we naturally feel more directly implicated in assessments of human behavior, but that human vs. nonhuman (or more precisely conscious vs. nonconscious) is a major motif in what Whorf terms the cryptogrammar of language.

Each of the three main categories is subdivided at increasingly delicate levels. For example, Affect may be *realis* (I like/hate it) or *irrealis* (I want/fear it); Judgment may involve social esteem (she is clever/stupid) or social sanction (she is honest/a fake); and Appreciation includes subcategories such as reaction (it is interesting/tedious) and composition (it is harmonious/a mess). Martin points out that Appreciation is the category most affected by field or subject area: whereas the judgments of humans fall into generally applicable groupings (we normally have a high degree of agreement on how people should and should not behave), the values at stake in, say, advertising a holiday resort are rather different from those in academic research. Nevertheless, it is argued that valid subcategories can be set up that hold over the wide diversity of linguistic realizations, and that the distinctions reflect culturally specific sets of values.

As previously noted, evaluation need not be explicit; and Appraisal theory builds in a distinction between inscribed and evoked appraisal. In (5), the inscribed appraisal relates to Atlantic City (*endless … excitement, world famous*), but the main purpose in mentioning this is that the proximity of Atlantic City is clearly intended as a token of appraisal to evoke positive Appreciation of the beach. Inscription and evocation of appraisal are not seen as distinct categories but as points on a cline; in the intermediate area, appraisal may be provoked by signals which are not in themselves evaluative but which indicate that evaluation is going on. In fact, (5) is an example of provoked Appreciation – the phrase *just minutes away* (more generally the frame *just [small measurement term] away*) is typically used in contexts that are evaluative rather than neutral statements of distance. A paraphrase of (5) that took away the provoking signals would still be read in context as an appreciation of the beach, but more implicitly evoked: *Brigantine Beach is close to Atlantic City's casinos and boardwalk*. As this version makes clear, evoked appraisal relies even more strongly than inscribed does on shared values; the reader is expected to collaborate in constructing the evaluation that makes this statement appear coherent in context. This serves to reinforce existing sets of values (casinos and boardwalks are attractive; proximity to them is a bonus), and it may also, of course, be used for manipulative purposes by not spelling out the values that the addressees are being projected as already sharing.

Evaluative Voices

If we turn now to the role of evaluation in construing the relationship between writer and reader, this involves moving a step beyond the typical lay view of evaluation as purely I-oriented, the self-justifying broadcasting of inner feelings. Evaluation should be seen rather as an essentially interactive resource, deployed in order to elicit a response, preferably of acceptance, from the addressee. To evaluate means to enter into a complex negotiation of values because any assessment inherently implies the possibility of a different assessment. That alternative assessment may be one that is already present in some sense – the writer may be reacting to assessments that have previously been spoken or written or that are represented as accepted truths; and/or it may be an assessment that the writer foresees as a potential response to his or her own assessment. The result can be a multilayering of evaluative voices, as in the following extract (from Trevor Phillips, 'Multiculturalism's legacy

is "have a nice day" racism,' *The Guardian*, 28 May 2004).

> (1) This was a debate waiting to happen. (2) Some on the left had been worrying aloud for months that 'immigrants' are doomed to become ghetto-bound minorities, a divisive presence threatening Britain's underlying social fabric. (3) They need to relax. (4) All but the racist fundamentalists of the far right accept that Britain's economic and social vigour has always been renewed from the wellspring of immigration. (5) Scotland's first minister, Jack McConnell, sensibly wants new migrants to revive Scotland's relatively elderly population. (6) Even Norman Tebbit recently stunned a BBC audience with a warm and unqualified welcome to migrants from eastern Europe. (7) The real argument is how we manage the process of integrating migrants.

Some of the statements here are the writer's: *This was a debate waiting to happen* (1), *They need to relax* (3), and so on. Other statements are attributed (Sinclair, 1982, 1988; Tadros, 1993; Hunston, 2000) to other speakers: *some on the left* (2), *all but the racist fundamentalists of the far right* (4), *Scotland's first minister, Jack McConnell* (5), and *Norman Tebbit* (6). There is a far from simple distinction, however, between the I voice and the other voices in the extract. For example, the statement *Britain's economic and social vigour has always been renewed from the wellspring of immigration* (4) is attributed to a vaguely constituted group consisting of *all but the racist fundamentalists*, but the I voice of the extract clearly aligns himself with the statement, partly by constituting such a commonsense group and partly by choosing *accept* as the report verb. There is no such alignment with the group designated as *some on the left* (2). The I voice, then, is in consensus with the *all* voice but not with the *left* voice. The extract also construes conflict between the consensual group and the *racist fundamentalists*, whose implied voice is construed as saying that *Britain's economic and social vigour has not been renewed from the wellspring of immigration*.

White's theory of engagement addresses the question of how writers reflect their awareness of possible conflict and consensus or attempt to preempt the emergence of alternative assessments. A range of linguistic phenomena, including modality, polarity, and evidentiality, are seen as resources by which the writer may contract or expand the dialogic interaction. Contraction in White's model means closing down alternatives, presenting the evaluation as not open to negotiation, whereas expansion means opening up the dialog to alternative possibilities. The next two extracts (from *The Guardian Weekend* magazine, 22 May 2004) illustrate the difference. The first is an attack on aspects of political correctness and the second is a restaurant review.

> This is <u>surely</u> an example of excessive squeamishness. <u>I don't see how</u> press hysteria about 'bogus' asylum seekers can be allowed to discredit the phrase asylum seeker any more than indolence and scrounging among 'job-seekers' should discredit that expression.

> My lack of excitement stemmed not from any disappointment in the standard of the dim sum themselves. . . . The trouble was, I felt I'd come across it all before at Hakkasan. <u>Perhaps</u> this is an unsportsmanlike criticism to make. . . .

The underlined phrases in the first extract represent the evaluation as a matter of common agreement (*surely*) and the opposing view as patently wrong (*I don't see how*). In the second extract, on the other hand, the writer uses modality (*perhaps*) to signal that he is introducing a counterview that other people, including some readers, might advance, thus opening the discourse to alternatives. In both extracts, the negotiation is dialogic in that the views of others are explicitly acknowledged and engaged with.

More generally, the role of evaluation in construing negotiation raises the issue of which evaluation is mainly at stake at any point in the discourse; that is, what it is that the writer is negotiating. Evaluation can often be layered in complex ways, with one evaluative expression functioning as the stimulus for, or a token of, a different kind. This phenomenon, which might be called the Chinese box (or Russian doll) syndrome, appears to be an inherent feature of evaluation. If we go back to the Brigantine Beach extract, the text as a whole clearly functions as an appraisal of the beach, and in this context it can be argued that the judgment of *our community* as *friendly* is primarily a token of Appreciation – it provides grounds for appraising the resort positively. It is therefore similar to the appreciation of Atlantic City's *casino excitement* and *world famous boardwalk*, which in this text serves the same purpose. But should we stop there? The headline construes the appraisal in terms of Affect; so it would be equally valid to argue that the Appreciation (into which the Judgment feeds) functions primarily as grounds to justify the positive Affect that frames the text. The insight that evaluation is frequently nested in this way is a powerful one – but it can lead to a situation in which the analyst is uncertain how far to track the nesting or how to represent nested evaluation (as previously noted, this is especially pertinent in studies that take a quantitative approach).

Evaluation and Epistemic Knowledge

One of the difficulties in referring to evaluation as participating only in the interpersonal metafunction, as argued by Martin and White, is that it makes it appear additional to the information-giving function of a text. In fact, and especially in academic discourse, evaluation plays a central role in the construction of epistemic knowledge.

As previously mentioned, academic texts often express values of 'good' and 'bad' only very implicitly. Hunston (1989, 1994) points out that in most academic texts the success of an experiment or the failure of a rival researcher to take an essential factor into account is indicated through the grounds for assessing quality rather than through the assessment itself (in Martin's terms, it is evoked rather than inscribed). On the other hand, academic texts consistently present an assessment of the statements they consist of in terms of the relationship between the word and the world. Hunston refers to this as evaluation of status; the status of a proposition is the averred (not actual) alignment between it and the world outside the text. Because propositions have status, they construe the epistemological world as viewed by the writer.

Here is an illustrative extract, with sentences numbered and key phrases underlined as before (from Allaboutcircuits).

> (1) When Benjamin Franklin made his conjecture regarding the direction of charge flow (from the smooth wax to the rough wool), he set a precedent for electrical notation that exists to this day, despite the fact that we know electrons are the constituent units of charge, and that they are displaced from the wool to the wax— not from the wax to the wool—when those two substances are rubbed together. (2) This is why electrons are said to have a *negative* charge: because Franklin assumed electric charge moved in the opposite direction that it actually does, and so objects he called 'negative' (representing a deficiency of charge) actually have a surplus of electrons.

In this paragraph, the writer evaluates the status of a number of propositions, evaluating some as being Franklin's wrong ideas and others as today's knowledge. In other words, Franklin's ideas are assessed as aligning with a counterfactual world, whereas the contrasting ideas align with a factual one. The convention that electrons have a negative charge is neither factual nor counterfactual but might be called afactual. The status of each proposition is indicated by a noun (e.g., *conjecture*, 1), a verb (e.g., *know*, 1), or an adverb (e.g., *actually*, 2). The propositions and their statuses can be set out as in Table 2.

Status is clearly associated with evaluation of certainty – Franklin's conjecture is less certain than today's knowledge – but it is essentially about averred alignment rather than about certainty. The textual function of status evaluation is to reify propositions so that they can be further evaluated. In the Allaboutcircuits extract, Franklin's conjecture is evaluated as untrue not by being evaluated as a conjecture but by being asserted to be inconsistent with more recent, detailed knowledge. In academic discourse, the entity being evaluated is very commonly a proposition such as this rather than a physical object or a person.

In other types of discourse, evaluated entities are likely to be things (objects, organizations, people, and so on) rather than propositions. In the BNP *Guardian* extract, the BNP has the status of a political party. This is the kind of thing that it is, and it is evaluated in the terms appropriate to a party, notably the reasonableness of its policies and the respectability of its members. Other criteria for judging political parties include something that might be called gravitas; in (8) the mainstream parties are criticized for not achieving that. However, that text also puts forward propositions with an epistemic status, which are open to further evaluation. For example, the statement

Table 2 Evaluation of status

Aligned with a counterfactual world	Aligned with a factual world	Aligned with an afactual world	Status indicator
Electrical charge flows from smooth wax to rough wool			*conjecture*
	Electrons are the constituent units of charge. Electrons flow from wool to wax		*we know*
		Electrons have a negative charge	*are said*
Electrical charge moves in one direction			*assumed*
	Electrical charge moves in the other direction		*actually*
Objects are negative			*he called*
	These objects have a surplus of electrons		*actually*

But what is also needed to stop a national disaster in London is a determined push by all the mainstream parties (7) is a recommendation, for which further evidence is then given. The averred alignment between the proposition and the world is not factual, as in the Allaboutcircuits extract. Instead, the status is one of opinion: The statement is averred to be an interpretation of the world rather than a representation of it.

Analyzing Evaluation in Text

Evaluation, then, is a complex phenomenon that resists easy categorization. It demands objective recognition, yet time and again the interpretation of a phrase as evaluative is subjective and dependent on textual, situational, and cultural context. It demands systematicity, but systems that depend on generalization tend to oversimplify. It demands quantification, but also a response to the detail of individual discourses. It is, however, an essential object of study in any functional approach to language if linguists are to obtain a rounded picture of how discourse functions.

Evans, Gareth (1946–1980)

S-H Seong, University of Bonn, Bonn, Germany

© 2006 Elsevier Ltd. All rights reserved.

Gareth Evans was a philosopher of language and mind at Oxford University during the 1970s. From 1973 on Evans published important articles that dealt with such themes as the philosophy of language, logico-semantics, espistemology, and metaphysics. His unfinished main work, *The Varieties of Reference,* in which 'the Generality Constraint' as well as the notion of 'nonconceptual content' were introduced, was published posthumously by John McDowell in 1982. Influenced by Strawson and Davidson in the 1960s and 1970s, Evans developed theories for formal semantics for natural languages. Davidson's views on theory of meaning, i.e., theory of truth conditions and Dummett's interpretation of the German philosopher Frege had a special influence on the theoretical development of Evans's thought. He coedited *Truth and meaning* with John McDowell and published several variously influential articles in the areas of the philosophy of language and the philosophy of mind.

It is maintained that Evans belongs to the neo-Fregean position in the philosophy of language in the sense that he attempted to clarify the concepts and terms of Frege. The new theory of causal reference by Kripke and the theories of Direct Reference by Kaplan and Perry assume that the meaning of proper names and indexical and demonstrative expressions cannot be equated with a denoting description, since these expressions are restricted to their causally or contextually determined reference. Therefore, Frege's concept of 'sense' (*Sinn*) is claimed to be irrelevant for all these expressions. On the contrary, Evans observes that this way of criticizing Frege is based on the misunderstanding of Frege's theory and his concept of *Sinn*. According to Evans, Frege himself represents the position that the aforementioned expressions in question are directly referential.

The central thesis of *Varieties of Reference* has to do with Evans setting out Russell's principle as a starting modus operandi of what thinking about an object requires. "[Russell's] principle is that a subject cannot make a judgment about something unless he knows which object his judgment is about. ... In order to make Russell's Principle a substantial principle, I shall suppose that the knowledge which it requires is what might be called discriminating knowledge: the subject must have a capacity to distinguish the object of his judgment from all other things" (Evans, 1982: 89). Evans justifies this principle by means of a salient attribute of thinking which he took over from his teacher Strawson. He names this attribute 'generality constraint.' Evans prefers to explain "the sense in which thoughts are structured ... in terms of their being a complex of the exercise of several distinct conceptual abilities." This constraint postulates that "if a subject can be credited with the thought that *a* is F, then he must have the conceptual resources for entertaining the thought that *a* is G, for every property of being G of which he has a conception" (Evans, 1982: 100–104). In order to think of *a*, one must have an association of *a*, and this association can also come to the surface in other thoughts.

Evans is also well known for introducing a fourth pronoun category – the E-type – which is distinguished from the traditional tripartite classification of pronouns. Pronouns of this fourth category represent the antecedent quantifier phrase but are not bound by it. This contribution has to do with analyzing the environments in which there are good pragmatic reasons (not syntactic reasons) to avoid bound anaphora while still intending coreference. In this finding, the semantics of bound pronouns is studied and their place in the pragmatic theory of coreference is clarified.

Evenki

I Nedjalkov, Institute of Linguistic Research, St Petersburg, Russia

© 2006 Elsevier Ltd. All rights reserved.

Evenki belongs to the Tungusic family, widely considered to form a branch of the Altaic languages. Tungusic family comprises three subgroups, the Northern (or Siberian), the Southern (or Amur), and the Manchu. (There is another classification in which two subgroups are distinguished, the Northern group and the Southern group including Manchu.) The number of native speakers of Evenki in Russia does not exceed 30 000. Evenks live on vast territories in Siberia, far east of Russia, and in the north of China and Mongolia (where they are called Oroqs or Orochons; about 12 000). The Evenki Autonomous Region comprises about 768 000 square kilometres; its population is about 30 000 and only about 5000 of them are Evenks. If we sum up all the territories of Siberia and the far east of Russia inhabited by the Evenks, the total will equal the territory of at least one-third of Russia. There is hardly another people in the world as small as the Evenks that is aboriginal to such a vast area, as they were a nomadic people.

Evenki is also remarkable for its number of dialects and subdialects, about 50 in all. They are subdivided into three groups, Northern, Southern, and Eastern. The Northern dialects of Evenki are spoken in the northern part of the Krasnojarsk and Irkutsk regions, and the Southern dialects around Lake Baikal and in Buryatia. The Eastern dialects are spoken in the Republic of Sakha-Yakutia, in the Amur and Khabarovsk regions and on the Island of Sakhalin. The Evenki language acquired its writing system in the early 1920s. It was based on the Latin alphabet but later (in the early 1930s) it was replaced by the Cyrillic alphabet. Nowadays, books and newspapers are published in Evenki.

General Characteristics: Sentence Structure and Morphonology

Evenki is an agglutinating (suffixal) language with no prefixes. It has nonrigid SOV word order, rich verbal morphology, and predominantly participial and converbal syntax. Adjectives, demonstrative, and possessive pronouns, and numerals always precede the head noun.

Case, Number, and Possessivity

The Evenki noun has 13 cases (plus the comitative, which can also be viewed as a special noncase form). Nominative: zero marker (marks the subject); Accusative 1: *-va* (marks the definite direct object); Accusative 2: *-a/-ya* (marks the indefinite direct object; can also express the partitive meaning and, with markers of personal or reflexive possession, the benefactive meaning of the direct object); Dative: *-du/-tu* (marks locative and temporal adverbials and also addressee and beneficiary); Allative 1-*dula/-tula/-la;* Allative 2: *-tki;* Allative-Prolative: *-kli;* Locative-Allative:*-kla;* Instrumental: *-t/-di;* Ablative 1: *-duk/-tuk;* Ablative 2: *-git;* Prolative: *-duli/-li;* Comitative: *-nun*.

Accusative 2 (traditionally termed indefinite accusative) is used either for indefinite nonreferential objects or for a partitive meaning, and it generally occurs either with the future tense or with the imperative; e.g.,:

(1) *Ukumni-ye* *min-du* *bu:-kel*
milk-ACC2 I-DAT give-IMPERATIVE:2SG
'Give me some milk'

Accusative 2 with the markers of personal possession codes object-oriented benefactive forms, while the same case with reflexive-possessive markers codes subject-oriented benefactive forms, e.g.,: dy*av-ya-v* 'a boat for me', dy*av-ya-s* 'a boat for you'(SG); *dyaw-ya-vi* 'a boat for oneself (myself/yourself/himself/herself)'; dy*av-ya-var* 'a boat for ourselves/yourselves/themselves.' The plural marker is the suffix *-l* on the absolute majority of nominal stems; on nouns with the stem-final *-n*, the plural marker is *-r*, which ousts *-n*, e.g., *oron* 'reindeer.SG' → *oro -r* 'reindeer-PL'. The personal-possessive affixes are: dy*u-v* 'my house', dy*u-vun* 'our (EXCL) house'; dy*u-t* 'our (INCL) house', dy*u-s* 'your (SG) house', dy*u-sun* 'your (PL) house', dy*u-n* 'his/her house', dy*u-tyn* 'their house.' Reflexive-possessive affixes are *-vi/-mi* for a singular possessor: depending on the person of the subject it may mean 'my', 'your (SG), 'his/her'; and *-var/-mar* for a plural possessor: depending on the person of the subject it may mean 'our', 'your (PL)', or 'their'. Morphemic ordering in nouns is the following: noun stem - plural - case - possession, e.g.,: dyu-l-dula-tyn 'to their houses/tents'.

Tense/Aspect System and Agreement

There are eight tenses; the markers are: *-ra*: non-future tense; *-dyara*: present tense; *-cha:* past tense; *-dyacha:* imperfect; *-ngki:* iterative past; *-dya:* future 1; *-dyanga:* future 2; *-dyalla:* future 3. There are about 10 aspectual markers: imperfective *-dya*; inchoative *-l*; semelfactive *-sin/-sn/-s;* distributive *-kta;* durative *-t/ -chi;* habitual *-ngna;* iterative *-van/-vat;* resultative *-cha;* quick action *-malcha*.

Table 1 Agreement markers

	Nominal type		*Verbal type*	
	SG	*PL*	*SG*	*PL*
1st p.	*-v*	*-vun/-t*	*-m*	*-v/-p*
2nd p.	*-s*	*-sun*	*-nni*	*-s*
3rd p.	*-n*	*-tyn*	*-n*	*-ϕ*

There are two types of agreement. The first one coincides with the personal possession nominal markers and is used with tense forms that go back to (and coincide with) participles. The second type is the system of verbal agreement markers proper. Agreement markers of the finite verb forms are the following (see **Table 1**).

Non-finite Verb Forms

There are about 15 converbs and 10 participles. The most common participles are the habitual (marker-*wki*), the simultaneous (*-dyari*), the anterior (*-cha*), the posterior (*-dyanga*). The most common converbs are those of anteriority (marked by *-ksa/kanim*) and temporal-conditional converbs in *-mi (same-subject)* and *-raki (different-subject)*.

Voice System, Means of Valency Change, and Their Combinability

There are four productive means of changing the valency and/or the number of participants, traditionally regarded as voices: causative (marker *-vkan*), passive/decausative *(-v/-p/-mu*), reciprocal (*-mat/-mach*), and sociative. The sociative marker *-ldy* does not change syntactic valency of the base verb, but it changes the number of participants. Reflexivity is expressed pronominally. In this respect, Evenki, like other Tungusic languages, differs from the neighboring Turkic languages and reveals similarity to the neighboring Mongolian languages.

Causative derivation increases the valency of the base verb by one. Causatives are freely derived from all pure transitive and intransitive stems (i.e., stems with no other voice/valency suffixes) and also from sociatives and a few reciprocals, e.g.,: *iche-* 'to see sth' → *iche-vken-* 'to show sth to sb' → *iche-vken-met-* 'to show sth to each other'; *archa-* 'to meet sb' → *archa-mat-* 'to meet each other' → *archa-machi-vkan-*'to cause/let/make sb (to) meet each other'.

Sociative derivation is possible from all pure verb stems and also from causatives, but not from reciprocals and passives:

(2) *Asa-l* *dyu-va*
woman-PL house-ACC
iche-vke-ldy-re-0
see-CAUS-SOC-NFUT-3PL
'The women showed the house [to someone else] together'

Passive derivation (suffix *-v*) is possible from all transitive stems including causatives (thus resulting in either personal or impersonal passive constructions), almost all intransitives (resulting in impersonal passive constructions only) and seven intransitive 'weather' verbs (resulting in personal adversative passives). The marker *-v* homonymous with the passive suffix can function as a nonproductive causative suffix. Passives are not derived from reciprocals and sociative stems.

(3a) *Asi* *dyu-va* *o:-ra-n*
woman house-ACC make-NFUT-3SG
'The woman put up a tent'

(3b) Dy*u* *o:-v-ra-n*
tent make-PASS-NFUT-3SG
'The tent was put up'/'The house was built'

Reciprocal derivation is impossible from passive and sociative stems (the suffix *-ldy-met* is not a reciprocal derivation from sociative but a complex reciprocal suffix). It is possible from causative stems:

(4a) *Asa-l* *dyu-l-var*
woman-PL house-PL-their
iche-vken-met-te-0
see-CAUS-REC-NFUT-3PL
'The women showed their houses to each other'

(4b) *Nungartyn* *eme-vken-met-chere-0*
they come-CAUS-REC-PRES-3PL
'They cause each other to come'

Anticausatives from verbs denoting destruction or change of state are formed by means of the suffix *-rga/-rge*. From a small group of verbs, anticausatives are formed by means of the suffix *-v/-p/-mu*, and it also functions as a passive marker (note that this very suffix is also used to derive causatives from about 50 intransitive and 20 transitive verbs):

(5a) *kapu-* 'to break' (vt) → *kapu-rga* 'to break' (vi)
ety 'to tear' (vt) → *ety-rge* 'to tear' (vi)

(5b) *das*- 'to close' (vt) → *dasi-v*- 'to close' (vi)
sukcha 'to break' (vt) → *sukcha-v*- 'to break' (vi)

Negation, Modality Markers, and Morphemic Ordening

There are two major ways of expressing negation in Evenki: (a) by means of the conjugated negative auxiliary verb e -'not to . . .', and (b) with the negative noun *achin* 'no'.

The modality markers include: *-mu* ('want'), *-ssa* ('try'), and *-na* ('go'), e.g., Nungan homoty-va (ACC1) va: -na-ssa-mu-dyere-n lit. 'He wants to try to go and kill the bear'.

Morphemic ordening in verbs is the following: verb stem - causative - sociative - reciprocal - aspect - passive - modality - evaluation - aktionsarten - tense or non-indicative moods or nonfinite markers - subject agreement (in person/number).

Event-Based Semantics

P Lasersohn, University of Illinois at Urbana-Champaign, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

The notion of *events* may be used in semantic theory in a wide variety of ways, but the term *event-based semantics* normally refers to semantic analyses that incorporate or adapt the proposal of Davidson (1967) that certain predicates take an implicit variable over events as an argument. In Davidson's original proposal, this event argument is accommodated by analyzing the predicate as having one more argument place than is assumed in more traditional analyses. The event variable is existentially quantified, with the result that Sentence (1)a is assigned a logical structure like (1)b, rather than the more traditional (1)c:

(1) a. Jones buttered the toast.
b. $\exists e$ butter(Jones, the toast, e)
c. butter(Jones, the toast)

Thus, *butter* is analyzed as expressing a three-place relation between an individual who butters, an object that gets buttered, and a buttering event; and the sentence is analyzed as asserting that such an event exists.

The initial motivation for this proposal is that it provides a way to analyze adjuncts such as locative, temporal, and instrumental adverbial phrases. These are also treated as predicates of events – or more specifically as predicates of the same event as the verb. Each adjunct gives rise to its own clause in logical structure, and these are combined with the clause corresponding to the verb and its arguments by ordinary propositional conjunction. The existential quantifier binding the event variable takes scope over the whole structure, so that Sentence (2)a is assigned a logical structure like (2)b, for example:

(2) a. Jones buttered the toast with a knife in the bathroom at midnight.
b. $\exists e$[butter(Jones, the toast, e) & with(e, a knife) & in(e, the bathroom) & at(e, midnight)]

This approach has an advantage over one in which the adverbials are treated as arguments of the verb, so that *butter* expresses a five-place relation as in (3):

(3) butter(Jones, the toast, a knife, the bathroom, midnight)

If we adopt a formula like (3), but continue to represent *Jones buttered the toast* as in (1)c, with a two-place relation, we would seem to deny that *butter* expresses the same meaning in both sentences and claim instead that it is ambiguous. Nor is this a simple two-way ambiguity; *butter* will have to express different relations in each of the sentences in (4)

(5b) *das*- 'to close' (vt) → *dasi-v*- 'to close' (vi)
sukcha 'to break' (vt) → *sukcha-v*- 'to break' (vi)

Negation, Modality Markers, and Morphemic Ordening

There are two major ways of expressing negation in Evenki: (a) by means of the conjugated negative auxiliary verb e -'not to . . .', and (b) with the negative noun *achin* 'no'.

The modality markers include: *-mu* ('want'), *-ssa* ('try'), and *-na* ('go'), e.g., Nungan homoty-va (ACC1) va: -na-ssa-mu-dyere-n lit. 'He wants to try to go and kill the bear'.

Morphemic ordening in verbs is the following: verb stem - causative - sociative - reciprocal - aspect - passive - modality - evaluation - aktionsarten - tense or non-indicative moods or nonfinite markers - subject agreement (in person/number).

Event-Based Semantics

P Lasersohn, University of Illinois at Urbana-Champaign, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

The notion of *events* may be used in semantic theory in a wide variety of ways, but the term *event-based semantics* normally refers to semantic analyses that incorporate or adapt the proposal of Davidson (1967) that certain predicates take an implicit variable over events as an argument. In Davidson's original proposal, this event argument is accommodated by analyzing the predicate as having one more argument place than is assumed in more traditional analyses. The event variable is existentially quantified, with the result that Sentence (1)a is assigned a logical structure like (1)b, rather than the more traditional (1)c:

(1) a. Jones buttered the toast.
b. $\exists e$ butter(Jones, the toast, e)
c. butter(Jones, the toast)

Thus, *butter* is analyzed as expressing a three-place relation between an individual who butters, an object that gets buttered, and a buttering event; and the sentence is analyzed as asserting that such an event exists.

The initial motivation for this proposal is that it provides a way to analyze adjuncts such as locative, temporal, and instrumental adverbial phrases. These are also treated as predicates of events – or more specifically as predicates of the same event as the verb. Each adjunct gives rise to its own clause in logical structure, and these are combined with the clause corresponding to the verb and its arguments by ordinary propositional conjunction. The existential quantifier binding the event variable takes scope over the whole structure, so that Sentence (2)a is assigned a logical structure like (2)b, for example:

(2) a. Jones buttered the toast with a knife in the bathroom at midnight.
b. $\exists e$[butter(Jones, the toast, e) & with(e, a knife) & in(e, the bathroom) & at(e, midnight)]

This approach has an advantage over one in which the adverbials are treated as arguments of the verb, so that *butter* expresses a five-place relation as in (3):

(3) butter(Jones, the toast, a knife, the bathroom, midnight)

If we adopt a formula like (3), but continue to represent *Jones buttered the toast* as in (1)c, with a two-place relation, we would seem to deny that *butter* expresses the same meaning in both sentences and claim instead that it is ambiguous. Nor is this a simple two-way ambiguity; *butter* will have to express different relations in each of the sentences in (4)

(4) a. Jones buttered the toast with a knife.
b. Jones buttered the toast in the bathroom.
c. Jones buttered the toast at midnight.
d. Jones buttered the toast with a knife at midnight.
e. Jones buttered the toast with a knife in the bathroom.
f. Jones buttered the toast at midnight in the bathroom.

This massive ambiguity is undesirable.

We might try to avoid the ambiguity by claiming that *butter* always expresses a five-place predicate, and that in examples in which fewer than five arguments appear overtly, the missing argument places are filled by implicit existentially bound variables. However, this strategy ignores the fact that additional adverbials can always be added, with no limit on the number; as long as adverbials are analyzed as arguments, one cannot specify a fixed number of argument places for the verb, even if one allows for implicit arguments.

These problems are avoided completely under Davidson's proposal; *butter* is consistently analyzed as a three-place predicate. An unlimited number of adverbials may be added because these combine with the verb by ordinary conjunction, and not by filling argument places.

A second advantage to this analysis is that it correctly captures the fact that Sentence (2)a entails all the examples in (4) as well as (1)a, that (4)d entails (4)a, (4)c, and (1)a, and so on. Without some extra stipulation, these entailment relations do not fall out of an analysis in which adverbials are arguments to the verb. Extra stipulations are also required to capture these entailment relations in other alternative approaches to the semantics of adverbials, such as an approach in which they are treated as higher-order predicates taking verb intensions as arguments, as in (5):

(5) [at-midnight(^in-the-bathroom(^with-a-knife(^butter)))](Jones, the toast)

Davidson limited his original proposal to 'action sentences' and was explicit that it should not be applied to sentences such as $2 + 3 = 5$. Nonetheless, it is sometimes assumed that a similar analysis should be extended to some or all stative sentences (see especially Parsons, (1987/1988, 1990). In analyses employing both states and events, the term *eventuality* (introduced by Bach, 1986) is often used for the general category covering both.

The issue of which predicates have a hidden argument place for an eventuality, and which do not, is addressed in a well-known proposal by Kratzer (1995); see also Higginbotham (1983) and Fernald (2000). Kratzer suggests that *individual-level* predicates do not have such an argument place, and that *stage-level* predicates do. This position is supported by the following pattern of acceptability:

(6) a. When Mary speaks French, she speaks it well.
b. *When Mary knows French, she knows it well.
c. When a Moroccan speaks French, she speaks it well.
d. When a Moroccan knows French, she knows it well.

Assuming that indefinites contribute free variables to semantic representation (as in File Change Semantics or **Discourse Representation Theory**) and that *when*-clauses serve to restrict the domain of an implicit generic quantifier that can bind these variables, the acceptability of (6)c–d is expected. The unacceptability of (6)b follows from a simple prohibition on vacuous quantification: The *when*-clause contains no free variables for the generic quantifier to bind. Why, then, is (6)a acceptable, as it does not contain any indefinite noun phrases either? Kratzer suggests it is because the stage-level predicate *speak* contributes a free Davidsonian event variable, whereas the individual-level predicate *know* does not.

Another area in which event variables have proven useful is in the semantics of perception reports (Higginbotham, 1983; Vlach, 1983; Parsons, 1990). Sentences like (7)a have been cited in support of thoroughgoing revisions to semantic theory of the kind adopted in **Situation Semantics**; but if we analyze this sentence as meaning that there is an event e of Mary's leaving, and an event e' of John's seeing e, we may assign it the logical structure in (7)b and obtain a reasonable analysis without using resources beyond those of ordinary first-order logic:

(7) a. John sees Mary leave.
b. $\exists e[\text{leave}(\text{Mary}, e)\ \&\ \exists e'\ \text{see}(\text{John}, e, e')]$

Davidson's technique of representing adjunct phrases as expressing separate logical clauses raises the possibility that major arguments of the verb such as the subject, direct object, and so on, might be treated in the same way. Davidson himself rejected this sort of extension, but a variant of it has been very popular in later work. Often termed the *Neo-Davidsonian* approach, this style of analysis treats the verb as a one-place predicate of eventualities; the subject, direct object, and so on do not serve directly as arguments to the verb, but instead stand in thematic relations to an event that fills the verb's sole argument place. A sentence such as (8)a thus receives a logical structure like that in (8)b:

(8) a. Brutus stabbed Caesar.
b. $\exists e$[stab(e) & agent(e, Brutus) & patient(e, Caesar)]

This approach to thematic relations appears first to have been proposed by Parsons (1980, 1985, 1990); see also Carlson (1984) and Krifka (1989, 1992). Note that this style of analysis requires an eventuality argument for all predicates that assign thematic roles, not just action predicates or stage-level predicates – at least on the assumption that thematic roles are represented in a uniform fashion for all predicates that assign them.

One advantage of this approach is that it allows a nice analysis of 'semantically optional' arguments: The direct object of *stab* may be omitted, as in (9)a; to give a logical form, we simply omit the clause for the corresponding thematic relation, as in (9)b:

(9) a. Brutus stabbed.
b. $\exists e$[stab(e) & agent(e, Brutus)]

In a more conventional analysis, we might represent this sentence as in (10)a:

(10) a. $\exists x$ stab(Brutus, x)
b. stab(Brutus)

But as Parsons points out, this entails that Brutus stabbed something, whereas (9)a does not: Brutus could have stabbed and missed. If we try to avoid this entailment by representing (9)a as (10)b, we treat *stab* as ambiguous, expressing a different meaning in (9)a than it does in (8)a; but this is avoided in the Neo-Davidsonian analysis.

The idea that verbs are predicates of events has also been exploited in the analysis of certain types of nominalization (Higginbotham, 1985; Parsons, 1990). Combining the Neo-Davidsonian analysis with an assumption that nominals may express the same predicate of events as the verbs they derive from makes it possible to account for the validity of the argument in (11)a in a very straightforward fashion. This argument is represented as in (11)b, which is licensed by standard principles of first-order logic:

(11) a. In every burning, oxygen is consumed.
Agatha burned the wood.
Therefore, oxygen was consumed.
b. $\forall e$[burn (e) $\rightarrow \exists e'$ [consume(e') & theme (e', oxygen) & in(e, e')]]
$\exists e$[burn(e) & agent(e, Agatha) & patient (e, the wood)]
$\exists e'$[consume(e') & theme(e', oxygen)]

Event arguments have also been used extensively in the analysis of Aktionsart. One line of research in this area, exemplified by Pustejovsky (1991, 1995) and Grimshaw (1990), represents events of certain complex types as structurally composed of events of simpler types. For example, an accomplishment predicate such as *build* may be associated with events of the structure illustrated in (12):

(12)

Here e_1 represents the building process itself, whereas e_2 represents the resultant state of something having been built. As a telic predicate, *build* involves reference not just to the building process, but also to its culmination in the transition to a result state, represented by e_0.

A rather different approach to the event-theoretic representation of Aktionsart was developed by Krifka (1989, 1992). Here, a 'sum' operation is assumed on events, so that for any two events e_1, e_2, a complex event $e_1 \sqcup e_2$ consisting of them is assumed to exist. A part/whole relation is definable in terms of the sum operation: $e_1 \sqsubseteq e_2$ ('e_1 is a part of e_2') iff $e_2 = e_1 \sqcup e_2$. Predicates are assumed to denote sets of events, allowing aspectual classes to be defined in terms of closure conditions on these sets. Cumulative predicates are those denoting sets that are closed under the sum operation:

(13) $\mathrm{CUM(P)} \leftrightarrow \forall x, y\ [[\mathrm{P}(x)\ \&\ \mathrm{P}(y)] \rightarrow \mathrm{P}(x \sqcup y)]$

For example, if x is a walking event, and y is a walking event, their combination is also a walking event. In contrast, quantized predicates denote sets from which proper parts of their members are excluded:

(14) $\mathrm{QUA(P)} \leftrightarrow \forall x, y\ [[\mathrm{P}(x)\ \&\ \mathrm{P}(y)] \rightarrow x \not\sqsubset y]$

For example, if x is an event of drinking a glass of wine, and y is also an event of drinking a glass of wine, x cannot be a proper part of y. Cumulative and quantized predicates of events correspond roughly to the familiar categories of atelic and telic predicates, respectively. However, by assuming a sum operation and corresponding part/whole relation on individuals, and not just events, it is possible to apply these concepts to predicates of individuals as well. For example, if x is wine and y is wine, their sum must also be wine, establishing *wine* as a cumulative predicate; if x is a glass of wine and y is a glass of wine, x may not be a proper part of y, establishing *glass of wine* as a quantized predicate. The status of a verb's arguments as cumulative or quantized often affects the aspectual category of the verb phrase or sentence; hence (15)a is cumulative whereas (15)b is quantized:

(15) a. John drank wine.
b. John drank a glass of wine.

Assuming a Neo-Davidsonian representation of thematic relations, Krifka explored the mathematical properties such relations must have to give this effect.

A related application of part/whole structures for events was developed by Lasersohn (1990, 1995) for the semantics of plurality (see also Schein, 1993). Distributive readings of predicates with plural subjects are analyzed as representing events that divide into smaller events corresponding to the individual members of the group denoted by the subject. For example, an event of John and Mary sitting divides into a smaller event of John sitting and one of Mary sitting. Collective readings correspond to events that cannot be divided in this way; an event of John and Mary being a happy couple does not divide into an event of John being a happy couple and an event of Mary being a happy couple. Representing the collective/distributive distinction in terms of event structure in this way makes possible an extensional analysis of adverbials like *together*, which imposes a collective reading on the predicates it modifies.

Event-based semantics has also been fruitfully applied to a wide variety of other problems, of which space limitations prevent a discussion here: plurality (Lasersohn, 1990, 1995; Schein, 1993; Landman, 2000), temporal anaphora and narrative progression (Hinrichs, 1986; Partee, 1984), cognate objects (Mittwoch, 1998), adjectives (Larson, 1998), and many others. There is also a large philosophical literature on events, much of which relates directly to Davidsonian-style event-based semantics; see Davidson (1980), LePore and McLaughlin (1985), Higginbotham *et al*. (2000), and the references cited therein.

Evidentiality in Grammar

A Y Aikhenvald, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

Evidentiality is a grammatical category that has source of information as its primary meaning – whether the narrator actually saw what is being described, or made inferences about it based on some evidence, or was told about it, etc. Languages vary in how many information sources have to be marked. Many just mark information reported by someone else; others distinguish firsthand and nonfirsthand information sources. In rarer instances, visually obtained data are contrasted with data obtained through hearing and smelling, and through various kinds of inference.

As Boas (1938: 133) put it, "while for us definiteness, number, and time are obligatory aspects, we find in another language location near the speaker or somewhere else, source of information – whether seen, heard, or inferred – as obligatory aspects." The terms 'verificational' and 'validational' are sometimes used in place of 'evidential.' French linguists employ the term 'mediative' (Guentchéva, 1996). The term 'evidential' was first introduced by Jakobson (1957). A summary of work on recognizing this category, and naming it, is in Jacobsen (1986) and Aikhenvald (2004).

Evidentiality is a verbal grammatical category in its own right, and it does not bear any straightforward relationship to truth, the validity of a statement, or the speaker's responsibility. Neither is evidentiality a subcategory of epistemic or any other modality (pace Palmer 1986: 51): in numerous languages irrealis and other modalities can occur together with evidentials (also see discussion in De Haan, 1999; Lazard, 1999, 2001; and DeLancey, 2001).

In Tariana, an Arawak language spoken in the multilingual area of the Vaupés in northwest Amazonia, speakers have to specify whether they saw the event happen, or heard it, or know about it because somebody else told them, etc. Omitting an evidential typically results in an ungrammatical and highly unnatural sentence (see details in Aikhenvald, 2004).

If one saw José play football, (1) would be appropriate:

(1) Juse irida di-manika-**ka**
José football 3person.masculine.singular-play-RECENT.PAST.VISUAL
'José played football (we saw it)'

If one just heard the noise of a football game but could not see what was happening, (2) is the thing to say:

(2) Juse irida di-manika-**mahka**
José football 3person.masculine.singular-play-RECENT.PAST.NONVISUAL
'José played football (we heard it)'

If one sees that the football is not in its normal place in the house, José and his football boots are gone, with crowds of people coming from the football ground, these details are enough for us to infer that José is playing football:

(3) Juse irida di-manika-**nihka**
José football 3person.masculine.singular-play-RECENT.PAST.INFERRED
'José played football (we infer it from visual evidence)'

If José is not at home on a Sunday afternoon, we can safely say (4). Our inference is based on general knowledge about José's habits: he usually plays football on Sunday afternoon.

(4) Juse irida di-manika-**sika**
José football 3person.masculine.singular-play-RECENT.PAST.ASSUMED
'José played football (we infer it from general knowledge)'

If one learnt the information from someone else, then (5) – with a reported evidential – is the only correct option:

(5) Juse irida di-manika-**pidaka**
José football 3person.masculine.singular-play-REC.P.REP
'José played football (we were told)'

Languages that have 'evidentiality' as a grammatical category vary in how many types of evidence they

Evidentiality in Grammar

A Y Aikhenvald, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

Evidentiality is a grammatical category that has source of information as its primary meaning – whether the narrator actually saw what is being described, or made inferences about it based on some evidence, or was told about it, etc. Languages vary in how many information sources have to be marked. Many just mark information reported by someone else; others distinguish firsthand and nonfirsthand information sources. In rarer instances, visually obtained data are contrasted with data obtained through hearing and smelling, and through various kinds of inference.

As Boas (1938: 133) put it, "while for us definiteness, number, and time are obligatory aspects, we find in another language location near the speaker or somewhere else, source of information – whether seen, heard, or inferred – as obligatory aspects." The terms 'verificational' and 'validational' are sometimes used in place of 'evidential.' French linguists employ the term 'mediative' (Guentchéva, 1996). The term 'evidential' was first introduced by Jakobson (1957). A summary of work on recognizing this category, and naming it, is in Jacobsen (1986) and Aikhenvald (2004).

Evidentiality is a verbal grammatical category in its own right, and it does not bear any straightforward relationship to truth, the validity of a statement, or the speaker's responsibility. Neither is evidentiality a subcategory of epistemic or any other modality (pace Palmer 1986: 51): in numerous languages irrealis and other modalities can occur together with evidentials (also see discussion in De Haan, 1999; Lazard, 1999, 2001; and DeLancey, 2001).

In Tariana, an Arawak language spoken in the multilingual area of the Vaupés in northwest Amazonia, speakers have to specify whether they saw the event happen, or heard it, or know about it because somebody else told them, etc. Omitting an evidential typically results in an ungrammatical and highly unnatural sentence (see details in Aikhenvald, 2004).

If one saw José play football, (1) would be appropriate:

(1) Juse irida di-manika-**ka**
José football 3person.masculine.singular-play-RECENT.PAST.VISUAL
'José played football (we saw it)'

If one just heard the noise of a football game but could not see what was happening, (2) is the thing to say:

(2) Juse irida di-manika-**mahka**
José football 3person.masculine.singular-play-RECENT.PAST.NONVISUAL
'José played football (we heard it)'

If one sees that the football is not in its normal place in the house, José and his football boots are gone, with crowds of people coming from the football ground, these details are enough for us to infer that José is playing football:

(3) Juse irida di-manika-**nihka**
José football 3person.masculine.singular-play-RECENT.PAST.INFERRED
'José played football (we infer it from visual evidence)'

If José is not at home on a Sunday afternoon, we can safely say (4). Our inference is based on general knowledge about José's habits: he usually plays football on Sunday afternoon.

(4) Juse irida di-manika-**sika**
José football 3person.masculine.singular-play-RECENT.PAST.ASSUMED
'José played football (we infer it from general knowledge)'

If one learnt the information from someone else, then (5) – with a reported evidential – is the only correct option:

(5) Juse irida di-manika-**pidaka**
José football 3person.masculine.singular-play-REC.P.REP
'José played football (we were told)'

Languages that have 'evidentiality' as a grammatical category vary in how many types of evidence they

mark. Some distinguish just two terms (eyewitness and noneyewitness, or reported and everything else), while others six or more terms.

Every language has some lexical way of referring to information source, e.g., English *reportedly* or *allegedly*. Such lexical expressions may become grammaticalized as evidential markers. Nonevidential categories may acquire a secondary meaning relating to information source. Conditionals and other nondeclarative moods may acquire overtones of uncertain information obtained from some other source, for which the speaker does not take any responsibility; the best known example is the French conditional (Dendale, 1993). Past tense and perfects acquire overtones of nonfirsthand information in many Iranian and Turkic languages, and resultative nominalizations and passives (also with a resultative meaning) can express similar meanings. In other languages, the choice of a complementizer or a type of complement clause may serve to express meanings related to how one knows a particular fact. In English, different complement clauses distinguish an auditory and a hearsay meaning of the verb *hear*: saying *I heard Brazil beating France* implies actual hearing, while *I heard that Brazil beat France* implies a verbal report of the result. These evidential-like extensions are known as 'evidentiality strategies' (Aikhenvald, 2003a). Historically, they may give rise to grammatical evidentials.

Languages with evidentials fall into a number of subtypes, depending on how many information sources acquire distinct grammatical marking. Small systems with just two choices cover:

A1. Firsthand vs. nonfirsthand. The firsthand term typically refers to information acquired through vision (or hearing, or other senses), and the nonfirsthand covers all other sources, including information acquired by senses other than seeing, by inference and by verbal report. A useful overview of such systems, especially in Turkic and Iranian languages, is in Johanson and Utas (2000). In (6), from Jarawara, an Arawá language from Brazil (Dixon, 2003), a firsthand evidential marks what the speaker could see, and the nonfirsthand refers to what he could not see

(6) Wero kisa-me-**no**,
name get.down-BACK-IMMEDIATE.PAST.NONFIRSTHAND.masculine
ka-me-**hiri**-ka
be.in.motion-BACK-RECENT.PAST.FIRSTHAND.masculine-DECLARATIVE.masculine
'Wero got down from his hammock (which I didn't see), and went out (which I did see)'

A2. Nonfirsthand and everything else. The nonfirsthand evidential covers a large domain of information acquired through senses other than seeing, and through hearsay and inference of all sorts, as in many Caucasian languages, and also in Turkic and Finno-Ugric languages (Johanson, 2003; Aikhenvald, 2003a). Forms unmarked for evidentiality are evidentially neutral (they do not have any reference to information source). The nonfirsthand evidential in Abkhaz, a Northwest Caucasian language (Chirikba, 2003), can describe inference, as in (7): that the woman was crying is inferred from the fact that her eyes are red. The same form is used for reported information.

(7) jə-q'a-n d'ᵒəwa-**zaarən**
it-be-PAST (s)he+cry-NONFIRSTHAND
'(when she came up to the light, to the fire, her eyes were very red) Apparently, she had been crying' (speaker's inference)

A3. Reported (or 'hearsay') and everything else. Systems of this sort with one, reported, evidential, which covers information acquired through someone else's narration, are widespread all over the world (see, for instance, Silver and Miller (1997: 38) on North American Indian languages). (8) comes from Estonian:

(8) Ta **olevat**
he be.REPORTED
arsti-teaduskonna
doctor-faculty.GENITIVE.SINGULAR
lõpeta-nud
finish-PAST.PARTICIPLE
'He is said to have completed his studies of medicine (but I wouldn't vouch for it)'

A4. Sensory evidence and reported. The sensory evidential refers to something one has seen, heard, smelt, or felt (by touch); the other evidential refers to verbal report, as in the Australian languages Ngiyambaa (Wangaaybuwan-Ngiyambaa) and Diyari (Dieri).

Of these, A1 and A4 are clear-cut two-term systems, while A2 and A3 include an 'everything else,' or evidentially neutral, term.

Systems with three choices are:

B1. Direct (or visual), Inferred, and Reported. Depending on the system, the first term can refer to visually acquired information, as in Qiang, a Tibeto-Burman language from China; or to information based on sensory evidence, which covers seeing, hearing, smelling and touching something, as in Mosetén, an isolate from Bolivia, the Jaqi, or Aymara languages

from Bolivia (Hardman, 1986), and Shilluk (a Western Nilotic language from Sudan). Quechua languages have three evidentiality specifications: direct evidence (*-mi*), conjectural (*-chi*, *-chr(a)*) and reported (*-shi*) (see Floyd, 1999, on Wanka Quechua:

(9) trabaja-aña-**m** li-ku-n
work-PURPOSE. MOTION-now-DIRECT. EVIDENTIAL go-REFLEXIVE-3person
'He's gone to work' (I saw him go)

(10) chay lika-a-nii
that see-NOMINALISER-1person
juk-ta-**chra**-a lika-la
other-ACCUSATIVE-CONJECTURAL. EVIDENTIAL-TOPIC see-PAST
'The witness ('my seer') must have seen someone else' (her house was robbed; she saw someone next to her house, it was not me, I infer it was (*-chr*) someone else)

(11) Ancha-p-**shi**
too.much-GENITIVE-REPORTED.EVIDENTIAL
wa'a-chi-nki
cry-CAUSATIVE-2person
wamla-a-ta
girl-1person-ACCUSATIVE
'You make my daughter cry too much' (they tell me)

B2. Visual, Nonvisual sensory, Inferred are found in Washo, from the California-Nevada border and in Siona, a West Tucanoan language from Ecuador.

B3. Visual, Nonvisual sensory, Reported are found in Oksapmin (isolate from Papua New Guinea), Maricopa, a Yuman language from Arizona, and Dulong, a Tibeto-Burman language from Burma.

B4. Nonvisual sensory, Inferred, Reported are found in the Samoyedic languages Nganasan and Enets.

B5. Reported, Quotative and everything else. Only reported and quoted information requires a special marker in a few North American Indian languages, e.g., Comanche, a Uto-Aztecan language from Oklahoma.

These systems include at least one sensory specification. The nonvisual sensory evidential in B2, B3, and B4 systems typically covers information acquired by hearing, smelling, and touching, and feeling. The inferred evidential refers to inference based on visible traces and assumption, while the reported evidential describes any kind of verbal report. If a language has an evidentially unmarked form, its evidentiality value is typically recoverable from the context.

Four-term systems cover:

C1. Visual, Nonvisual sensory, Inferred, Reported, as in numerous East Tucanoan languages spoken in northwest Amazonia, and in Eastern Pomo, a Pomoan language from California.

C2. Visual or direct evidence, Inferred, Assumed, REPORTED, as in Shipibo-Konibo, a Panoan language from Peru. The sensory evidential in a C2 system can refer to firsthand knowledge acquired through any physical sense, be it vision, hearing, smell, taste, or touch, as in Shipibo-Konibo; or it may refer just to information acquired by seeing, as in Tsafiki, a Barbacoan language from Ecuador (Dickinson, 2000). The visual evidential is formally unmarked; there is one suffix marking information inferred from direct physical evidence, another for inference from general knowledge, and an additional one for reported, or hearsay.

(12) Manuel ano fi-e
Manuel food eat-DECLARATIVE
'Manuel ate' (the speaker saw him)

(13) Manuel ano fi-nu-e
Manuel food eat-INFERRED-DECLARATIVE
'Manuel ate' (the speaker sees the dirty dishes)

(14) Manuel ano fi-n-ki-e
Manuel food eat-NOMINALISER-VERB.CLASS:do-DECLARATIVE
'Manuel ate' (He always eats at 8:00 and it's now 9:00)

C3. Direct (or visual) Inferred, Reported, Quotative are found in Cora, a Uto-Aztecan language from Mexico.

Four-term systems involve at least one sensory specification. If there is just one sensory evidential, additional complexity arises within inferred evidentials (as in C2: one evidential then refers to inference based on visible results, and the other one to inference based on reasoning and assumption). Additional choices between reported evidentials involve distinguishing reported and quoted information (C3).

The only type of multiterm system found in more than one language involves:

D1. Visual, Nonvisual sensory, Inferred, Assumed, and Reported. This system was exemplified in (1)–(5) above and is also found in Tucanoan languages in Brazil and Colombia, such as Tuyuca and Desano (Barnes, 1984).

Systems with more than five terms have just two sensory evidentials, and a number of evidentials based on inference and assumption of different kinds, as in the Nambiquara languages from Brazil, and Foe and Fasu, of the Kutubuan family spoken in the Southern Highlands of Papua New Guinea. In some languages, a wide variety of evidential meanings may be expressed in different slots of the verbal word or within a clause. Different evidentiality specifications are 'scattered' throughout the grammar, and by no means form a unitary category, as in Makah, a Wakashan language from Washington State (Jacobsen, 1986), in Eskimo languages and in Western Apache, an Athabaskan language from Arizona (de Reuse, 2003: 97).

Evidentials can be expressed with a wide array of morphological mechanisms and processes. There is no correlation between the existence of evidentials and language type. Even pidgins and creoles are known to have had evidentials (as did Chinese Pidgin Russian). Examples of a truly functionally unmarked form in an evidentiality system are rare. The firsthand, visual, or a combined visual and sensory, evidential tends to be less formally marked than any other term. This term is formally unmarked in some languages, as we saw in (12), from Tsafiki. Evidentiality neutral terms are a property of a few systems where an evidential is opposed to 'everything else' (these are A2, A3, A5, and B5). This is quite different from omitting an evidential, which can happen either if the information source is clear from the context, or if evidentials are mutually exclusive with some other morpheme, e.g., mood, as in Samoyedic languages.

Cooccurrence of different evidentials in one clause – and the different morphological statuses of evidentials – provides a tool for distinguishing evidentiality subsystems within one language. If a language has several distinct evidentiality subsystems, the reported specification is most likely to be set apart from others.

Evidentials differ from other grammatical categories in a number of ways. The information source can be marked more than once in a clause. Two sources can be different, but somehow linked together, as in Tsafiki (Dickinson, 2000: 408):

(15) Manuel ano **fi-nu-ti-e**
Manuel food eat-INFERENCE.PHYSICAL.EVIDENCE-REPORTED-DECLARATIVE
'He said/they say Manuel has eaten' (they didn't see him, but they have direct physical evidence)

In Eastern Pomo, the two sources can be fully distinct: describing information source of a blind man, one uses a nonvisual evidential, while the story is told in reported evidential because the narrator heard it from someone else. These features make evidentiality similar to a predication in its own right. Further arguments to the same effect include:

- An evidential may be within the scope of negation, as in Akha, a Tibeto-Burman language (Hansson, 2003). In (16), the visual experience and not the verb itself is being negated:

(16) àjɔq áŋ dì
he NOUN.PARTICLE beat
ɔ àshú yà mà ŋá
VERBAL.PARTICLE who not VISUAL
'I do not know/can't see who is beating him'

- An evidential can be questioned, as in Wanka Quechua (Floyd, 1999: 132).
- The 'truth value' of an evidential may be different from that of the verb in its clause. Evidentials can be manipulated to tell a lie. One can give a correct information source and wrong information, as in saying 'He is dead-REPORTED,' when you were told that he is alive, or correct information and wrong information source, as in saying 'He is alive-VISUAL,' when in fact you were told that he is alive, and did not see him die.
- And finally, an evidential can have its own time reference, distinct from the time reference of the event talked about (see Aikhenvald, 2003b, for Tariana).

Evidentials vary in their semantic extensions, depending on the system and its structure. The firsthand term in two term-systems typically refers to visual and often other sensory information, and can be extended to denote the direct participation, control, and volitionality of the speaker. The sensory evidential in A4 systems refers to sensory perception of any kind, without any epistemic or other overtones. The nonfirsthand term in A1 and A2 systems means the opposite of firsthand. The nonfirsthand often implies lack of participation, lack of control, nonspecific evidence (or no evidence at all), inference, and hearsay. An extension to hearsay is sometimes found but is not universal.

There are hardly any epistemic extensions in A1 evidentiality systems with two choices. Languages tend to have other ways of expressing probability and possibility.

In systems with three or more terms, the visual or the direct evidential usually covers information acquired through seeing, and also generally known and observable facts. It may be extended to indicate certainty. The nonvisual sensory evidential in B2, B3, and B4 systems refers to information acquired by

hearing, smell, touch, or feeling (such as an injection), and has no epistemic extensions. No language has a special evidential to cover smell but not auditory information. The inferred evidential typically covers inference based on visual evidence, on nonvisual sensory evidence, on reasoning or on assumption. It is also used to refer to someone else's 'internal states' – feelings, knowledge, and the like. It may acquire an epistemic extension of 'conjecture,' uncertainty, and lack of control.

The reported evidential is semantically uniform in systems of all types. Its core meaning is to mark that information comes from someone else's report. A reported evidential can be used as a quotative, to indicate the exact authorship of the information, or to introduce a direct quote. It can be used for a secondhand or thirdhand report. A reported evidential may develop an epistemic extension of unreliable information, as a means of 'shifting' responsibility for the information to some other source one does not vouch for, as in Estonian: example (8) has overtones of 'I don't vouch for this information.' Such extensions are not universal. As Valenzuela (2003: 57) remarks for Shipibo-Konibo, the selection of reported evidential over the direct evidential "does not indicate uncertainty or a lesser degree of reliability but simply reported information."

Languages with multiterm evidentials generally tend to have a multiplicity of other verbal categories, especially ones that relate to modalities. The larger the evidential system, the less likely it is that the evidential terms will develop epistemic extensions.

A nonfirsthand term in a two-term system, or an inferred term in a three-term system, tend to subsume all sorts of information acquired indirectly. These evidentials may then evolve mirative extensions (to do with unexpected information, the 'unprepared mind' of the speaker, and speaker's surprise: DeLancey, 1997, 2001).

When used with a first person subject, the nonfirsthand evidentials in A1 and A2 systems, nonvisual evidentials in larger systems, and reported in systems of varied types may acquire additional meanings of lack of intention, control, awareness, and volition on the part of the speaker. Verbs covering internal states may require obligatory evidential choice depending on person. As a result of these correlations evidentials acquire the implicit value of person markers.

Evidentials interrelate with clause types and other grammatical categories in the following ways:

1. The maximum number of evidential specifications tends to be distinguished in declarative main clauses.
2. The most frequent evidential in commands is reported ('do what someone else told you to'). The choice of an evidential in questions may contain reference to the source of information available to the speaker, to the addressee or to both.
3. Fewer evidentials may be used in negative clauses than in positive.
4. Nonindicative modalities (conditional, dubitative and so on) may allow fewer evidential specifications than the indicative. In many languages, evidentials may not be used in future which is, by its nature, a kind of modality.
5. The maximum number of evidential specifications is expected in past tenses. In some languages, as in Jarawara (Dixon, 2003), firsthand and nonfirsthand evidentials are distinguished only in the past. The source of information for an event is often based on its result, hence the link between firsthand/nonfirsthand, on the one hand, and past, perfect, perfective, and resultative on the other.

Evidentials often come from grammaticalized verbs. The verb of 'saying' is a frequent source for reported and quotative evidentials, and the verb 'feel, think, hear' can give rise to a nonvisual evidential in large systems. Closed word classes – deictics and locatives – may give rise to evidentials, both in small and in large systems.

Evidentiality strategies involving past tenses and perfects, and nominalizations, can develop into small evidentiality systems (A1 and A2). The creation of a reported evidential may involve reanalysis of subordinate clauses (typically, complement clauses of verbs of speech) as main clauses (as in Estonian). Nonindicative moods and modalities may give rise to a term in a large evidentiality system; however, there are no examples of a modal system developing into a system of evidentials. This lack of evidence confirms the separate status of evidentiality and modality. Large evidential systems tend to be heterogenous in origin.

Evidentiality is a property of a significant number of linguistic areas, including the Balkans, the Baltic area, India, and a variety of locations in Amazonia (Aikhenvald and Dixon, 1998). Evidentials may make their way into contact languages, such as Andean Spanish (see papers in Hardman, 1981).

If several information sources are available – for instance, I both saw and heard a dog barking and later someone told me about it – any one of three evidentials can potentially be used: visual, nonvisual, and reported. In this situation, the visual evidential tends to be preferred. The genre of a text may determine the choice of an evidential. Traditional stories are typically cast in reported evidential. Evidentials

can be manipulated in discourse as a stylistic device. Switching from a reported to a direct (or visual) evidential creates the effect of the speaker's participation and confidence. Switching to a nonfirsthand evidential often implies a backgrounded aside. Evidentiality is interlinked with conventionalized attitudes to information and precision in stating the source of information (Hardman, 1981, 1986).

Introduction

An event related potential (ERP) is a transient fluctuation in the brain's electrical field generated by neural activity and induced, in language studies, by the presentation of a visual or auditory language stimulus. ERPs are the oldest noninvasive technique for imaging the activity and location of brain systems during language processing. ERPs complement and extend the imaging power of other prominent imaging technologies, which include magnetoencephalography (MEG), positron emission tomography (PET), and most recently, functional magnetic resonance imaging (fMRI). Each technique has its advantages and disadvantages, but all remain vital emerging technologies for understanding the functional organization of language in the human brain.

The major goals of ERP language imaging research are to understand how the human language faculty is anatomically and functionally organized in the brain, how it maps spoken, signed, or written language onto mental structural representations and meaning, how it interacts with other cognitive brain systems, how it breaks down or reorganizes due to trauma or developmental factors, and how innate neurodevelopmental constraints and specific language experiences interact to determine its neurobiological organization.

Linguistic and psycholinguistic theory have played prominent roles in guiding ERP research toward these goals. For example, one dominant theme of linguistic theory has been the division of the human language faculty into modular subtheories that function independently to generate phonology, syntax, and semantics. Debates about the psychological reality of modular subtheories have produced competing psycholinguistic proposals to explain how processing mechanisms may proceed either modularly or interactively, in sequence or in parallel, to build coherent linguistic representations in the brain during sentence comprehension. Contemporary ERP research provides a powerful methodology for testing competing processing theories.

As recording technology and analysis methods have become more sophisticated, ERP studies have yielded new and unprecedented detail about the cerebral locations, time-courses, and functional interactions of different domains of language processes. ERPs have helped to provide answers to major questions about the stages of sentence processing from perception to comprehension, the nature of semantic processing, the timing of syntactic operations, the distinct roles of each hemisphere in language processing, the neurobiology of developmental language disabilities, and the neurobiology of language-specific versus language-universal processes. This article illustrates the importance of ERP imaging to our rapidly growing understanding of the neurobiology of human language by presenting contemporary highlights of these contributions.

What is an ERP?

An ERP, in the context of typical language studies, is a short-lived (approximately 1–2 seconds) fluctuating electrical response produced by the brain, and recorded from electrodes resting on the scalp. It reflects neural activity associated with the sudden appearance and processing of a language stimulus. Typical stimuli may include language elements such as spoken or printed syllables, letters, words, or lexical signs from a visual-spatial language such as American Sign Language (ASL). The ERP provides moment-by-moment information about how the brain identifies and interprets the linguistic features of those language elements. When those elements are presented as parts of a sentence, the ERP reflects information about the roles those elements play in the structural and semantic mental representations of the entire sentence.

When ERPs are sampled from different places on the scalp, they can provide information about where the brain systems that build mental language representations are located. Historically, cost and time considerations have restricted most laboratories to the use of a few sparsely distributed electrodes to sample ERPs at different places on the scalp. Therefore, localizing language systems based on ERP data has tended to be a crude or sometimes misleading process. However, the advent of sophisticated microcomputers and advanced electrode system design during the last two decades have made affordable 'dense-array' scalp recording technology available, in which dozens or hundreds of electrodes can be quickly situated on a person's scalp. Dense-array recordings provide unprecedented spatial detail of the brain's surface electrical fields during language processing, and permit anatomically plausible localization of the neural mechanisms underlying a particular language process within the 3-dimensional geometry of the brain.

Figure 1A shows a human volunteer wearing a state-of-the-art 128-sensor dense-array electrode net

Figure 1 (A) 128-sensor HydroCel Geodesic Sensor Net (reproduced by permission of Electrical Geodesics, Inc.) (B) Example of an ERP to a visually presented word. (C) A 128-channel dense-array ERP data set showing superimposed ERPs to visually presented words at each electrode site from different conditions in a semantic sentence processing study (based on Frishkoff *et al.*, 2004; supplied by and printed with permission of the authors). (D) Graphic representation of the 3-D location and projection scalp electrical fields of 2 of 10 ERP sources recovered from the topographic pattern of the data set represented in **Figure 1C**. (Adapted from Figure 6 of Frishkoff *et al.*, 2004; reprinted with permission of the authors.)

manufactured by Electrical Geodesics, Incorporated (Tucker, 1993). Each of the 128 electrodes can record a single ERP, such as that shown in Figure 1B, in response to a language stimulus. Because the voltage amplitude of an ERP to a single stimulus is tiny compared with the simultaneously occurring EEG, the same type of language stimulus must be presented several times, a second or two of brain activity must be sampled each time, and the samples must be averaged together to cancel out the random background EEG fluctuations. When this is done, stable microvolt-scale negative and positive peaks appear that comprise the ERP.

The ERP peaks are produced by the electrical fluctuations contributed to the scalp electrical field by many separate neural networks, or sources, located throughout the brain and functioning during different, often overlapping time periods after the stimulus. Many of these networks of neurons comprise the neural substrates of specific language subsystems. They are activated or inhibited in real time by the sequence of processing demands of the language stimulus and the performance requirements of the language task. Some ERP peaks will therefore appear, disappear, or change in amplitude or latency as a function of the occurrence of different specific language processes in different experimental processing tasks, providing a direct real-time measure of the activity of those processes.

Figure 1C displays a full set of ERPs recorded from 128 sites on the scalp during a recent semantic sentence processing study by Frishkoff *et al.* (2004). At each scalp location, the ERPs from four different experimental types of language stimuli within sentences are overlapped for comparison. At some locations the four stimulus types produced almost identical ERPs, while at other locations the four ERPs had very different patterns. The timing and distribution, or topography, of such language-related waveform differences over the scalp provide the basic information necessary for imaging the underlying language systems producing them. By applying mathematically sophisticated tools for component analysis, topographic animation, and electrical source analysis to densely sampled waveform sets, the location of the multiple sources that generate the scalp potentials can be inferred and their separate influences on the surface electrical fields at each moment in time can be observed (Tucker *et al.*, 1994; Scherg, 1990). Figure 1D shows the 3-D locations (left) and the individual scalp electrical field projections (right) of two examples of the 10 sources identified by Frishkoff *et al.* (2004) that combined to produce the language-related waveform differences in the ERPs in Figure 1C.

Advantages of ERPs

Excellent Temporal Imaging

Although the term *imaging* typically connotes spatial or spatiotemporal representations of functional brain systems, ERPs are often selected for language studies because they provide excellent *temporal* imaging of language processes at their natural rate of progression, on the order of tens or hundreds of milliseconds. Temporal imaging simply means the detailed millisecond-by-millisecond resolution of the complex time-courses of language processes by the ERP waveform and its components, regardless of the number of electrodes placed on the scalp. Indeed, many studies are less concerned with identifying the neural source locations and cortical topographies of a language process than with imaging the basic time-course of that process in relation to other language processes in order to test specific processing theories. Many aspects of perceptual, attentional, phonological, syntactic, and semantic processing occur within a few hundred milliseconds after the stimulus. ERPs from only a few optimally chosen recording sites are often sufficient to accurately track the relative amplitudes and latencies of different ERP components associated with those processes. fMRI and PET techniques cannot resolve the time courses of those processes since they typically have time resolutions on the order of seconds.

Good Spatial Resolution

The ability of ERPs to adequately image the distribution of electrical fields over the surface of the scalp and to reveal anatomically plausible localizations of language systems depends directly on how densely electrodes are placed over the whole scalp. Dense sampling with an array of 128 electrodes typically resolves the useful range of ERP spatial frequencies and avoids significant technical reference problems that produce misleading localization of electrical sources (Srinivasan *et al.*, 1998; Tucker *et al.*, 1994).

Because many different source configurations can produce the same distribution of electrical fields over the scalp, accurately localizing neural sources of language-related ERP components typically requires constraints based on prior knowledge of additional localizing data from fMRI or PET activation patterns observed during similar language processing tasks (Scherg and Berg, 1991). The recent development of advanced methods for recording truly concurrent ERP and fMRI data promises to substantially improve the spatiotemporal imaging power of ERP data by providing direct activation maps of ERP component sources during language processing (Goldman *et al.*, 2000).

Selectivity of Components for Specific Representational Levels of Language Processes

In certain experimental paradigms, some ERP components are sensitive to specific representational levels of language processing and are produced by different sources in the brain (Friederici and Kotz, 2003; Martin-Loeches *et al.*, 2001; Neville *et al.*, 1992; Nevins *et al.*, 2004; Osterhout and Holcomb, 1992). The following components have become central to ERP language studies.

The N400 component (Kutas and Hillyard, 1980) is a broad negative deflection that arises between 300 and 500 ms after the presentation of a word in a sentence that is semantically incongruous with the rest of the sentence (e.g., 'The boy ate cookies and bicycles') compared with a semantically congruous word (e.g., 'The boy ate cookies and milk'). Figure 2 illustrates the N400. Because its amplitude varies as a function of manipulations that produce semantic priming and sentence-level semantic constraints (Kutas and Van Petten, 1994), the N400 has become a mainstay ERP tool for studying semantic integration in sentence processing and its interaction with other levels of linguistic representation, such as syntactic and lexical processes.

The early left anterior negativity (ELAN) arises about 150 to 200 ms poststimulus in response to phrase structure violations (e.g., when a verb appears in a sentence position where the preceding syntactic frame requires a noun). A somewhat later left anterior negativity (LAN), occurring around 350 to 500 ms, appears to reflect violations of agreement, case marking, and thematic role assignment (Coulson *et al.*, 1998; Friederici and Kotz, 2003).

The P600 component arises between 400 and 800 ms after a stimulus word that violates the syntactic constraints of its sentence context or that triggers a syntactic reanalysis to repair a misparsing of a grammatically correct but ambiguous sentence frame (Friederici *et al.*, 1993; Osterhout and Holcomb, 1992). The P600 is responsive to a wide range of syntactic violations (Hagoort, 2003). The P600 may reflect general syntactic integration processes that compare the ongoing language input with the syntactic predictions established by previous sentence structure (Kaan *et al.*, 2000). It may also reflect the effort required to attempt syntactic reanalysis to make sense of implausible thematic role assignments in syntactically correct sentences (Hoeks *et al.*, 2004).

Figure 2 The N400 component is a negative deflection produced by lexical items that are semantically incongruous with their sentence context (e.g., 'The boy ate cookies and bicycles.') compared with lexical items that are semantically congruous (e.g., 'The boy ate cookies and milk.')

The recognition potential (RP) is an ERP component peaking at about 250 ms that indexes the function of neural networks concerned with the initial processing of individual words, especially lexical semantic processing, and is functionally distinct from the N400 (Martin-Loeches *et al.*, 2001).

By using linguistically sophisticated materials based on coherent psycholinguistic models to elicit these and other classic ERP components, researchers have begun to address core issues regarding lexical processing and sentence processing theory and have had some success at modeling the associated underlying brain systems, as illustrated below.

Lexical Access

Lexical access refers to the retrieval of the orthographic, phonological, syntactic, and semantic features of individual words during language processing. Previous ERP studies of semantic or syntactic category distinctions between words generally indicate that lexical access occurs by about 250 ms after word presentation (Abdullaev and Posner, 1998; Dahaene, 1995; Pulvermuller *et al.*, 1999; Samar and Berent, 1986; Martin-Loeches *et al.*, 1999).

The neurobiological substrates of lexical access are as yet unclear. Several ERP studies indicate that the lexical category distinction between closed class items (e.g., articles, conjunctions, etc.) and open class items (e.g., nouns, verbs, etc. having specific semantic content) is available between 200 and 350 ms poststimulus, with left anterior systems involved in processing closed class items and posterior systems involved in processing open class items (King and Kutas, 1998; Neville *et al.*, 1997). However, it is unclear whether these effects reflect the earliest stage of syntactic and semantic lexical access, respectively (Keurs *et al.*, 1999). Recent ERP studies suggest that semantic lexical access involves early activation of the left cingulate area and left anterior frontal areas (Abdullaev and Posner, 1998; Ruz *et al.*, 2003), which may trigger activation of category-specific Hebbian

cell assemblies widely distributed throughout both anterior and posterior cortex (Pulvermuller *et al.*, 1999). Recent ERP dense-array source localization of the RP indicates that the lingual gyri, located within the extrastriate cortex at the base of the posterior temporal lobes, are involved in lexical semantic categorization (Martin-Loeches *et al.*, 2001).

Semantic Processing

Lexical, syntactic, and semantic ambiguities in sentences often complicate the construction of meaning during sentence processing. A classic psycholinguistic issue has therefore been how the appropriate meaning of ambiguous words is determined. The multiple meanings of ambiguous words in sentences (e.g., 'bank') are all activated in memory at once early in processing (e.g., Tanenhaus *et al.*, 1979). Therefore, the selection of appropriate word meaning and its integration into the larger meaning of the sentence must involve inhibition of the context-inappropriate alternative meanings of words after their retrieval from the lexicon. N400 priming effects confirm that, following lexical access of the multiple meanings of a word, the semantic context provided by the preceding words produces a powerful postlexical inhibition of the irrelevant alternative meanings (Chwilla and Kolk, 2003).

A recent dense-array ERP imaging study of the N400 illustrates in unprecedented detail how multiple brain networks coordinate their processing over time during semantic comprehension of phrases and sentences. Frishkoff *et al.* (2004) asked participants to read sentences containing phrases that were semantically well formed (congruous with the predicative selectional restrictions of verbs or adjectives, e.g., '... drink some coffee'), or semantically ill formed (incongruous with predicative selectional restrictions, e.g., '... drink some sky').

Figure 3 is a sequence of topographic 'snapshot' maps of the brain activity, reproduced from Frishkoff *et al.* (2004), which display the scalp electrical fields produced every 16 ms by congruous and incongruous words at the ends of sentences over the N400 time epoch from approximately 250 to 550 ms poststimulus. The middle row shows the location of the N400 response (blue shading), based on the difference of the congruous and incongruous word topographies, as it develops and migrates over the cortical surface in time. The N400 response originates early in semantic

Figure 3 Topographic scalp maps from the study of Frishkoff *et al.* (2004), reproduced with permission from the authors. These maps represent sequential time samples of the millisecond-by-millisecond changes in the topographic distribution of the scalp electrical fields for final words in sentences that were semantically congruous with the sentence context (top row) or semantically incongruous with the sentence context (bottom row). The middle row displays the orderly topographic changes in the electrical field pattern at the scalp specifically related to neural sources that processed the semantic difference between the congruous and incongruous words. These topographic changes reflect the sum of the individual projected field patterns of 10 separate neural sources, each following its own schedule of activation, as they contribute to the semantic analysis of the congruity of individual words in their semantic context.

processing near the medial frontal cortex around 250 ms, presumably after lexical access has already occurred. As semantic integration of the word meaning into the sentence context progresses, the N400 response migrates toward posterior cortex and becomes lateralized over the right hemisphere.

Source localization revealed that the earliest source sensitive to semantic congruity was localized to the left anterior cingulated cortex. Subsequently, left inferior prefrontal sources became activated, followed a few milliseconds later by right inferior prefrontal sources, and remained active for a sustained period of time between 250 and 800 ms. Sources in the mid-posterior cingulate and inferior temporal cortex became active for a more transient period between 350 and 450 ms. During this peak, the right inferior temporal sources became predominantly sensitive to semantic incongruity when it occurred at the end of the stimulus sentence but not in the middle of the stimulus sentence.

This dynamic pattern of overlapping source activations agrees with earlier studies suggesting that ventral frontal regions of the left hemisphere are engaged in the early stages of lexical semantic comprehension, including semantic selection and maintenance in working memory. Subsequently, postlexical predicative semantic integration occurs within classical temporal language cortex such as Wernicke's area and the paralimbic cortex. The sustained prefrontal source activations suggest that the lateral prefrontal cortex is involved in concept maintenance in working memory and in top-down regulation of ongoing semantic integration processes in the posterior association cortex, mediated by corticothalamic pathways and corticolimbic mechanisms.

The N400 word incongruity effects at the ends of sentences reflect both predicative violations (due to lexical selectional restrictions) and pragmatic violations (due to general conceptual discrepancies), whereas word incongruity effects in the middle of sentences primarily reflect predicative violations. The N400 lateralization facts suggest that right hemisphere processes are recruited only as a last resort to specifically provide potentially coherent nonliteral semantic (pragmatic) interpretations of strict predicative violations, based on the general conceptual content of the sentence (Frishkoff *et al.*, 2004).

The N400 to a final word incongruence produced by either a sentence or a discourse context shows qualitatively similar behavior and topography (Salman and Pratt, 2002; Van Berkum *et al.*, 1999), suggesting no neurobiological distinction between sentence and discourse level boundaries during context buildup. Intrasententially, however, the results of Frishkoff *et al.* (2004) suggest that N400 is multiply determined by different sources that have neurobiologically distinct roles for logical (predicative) versus pragmatic processing. Future dense-array studies that explore the equivalence of N400 source models for sentence-level versus discourse-level semantic processing when both logical and pragmatic violations are systematically manipulated at each level will help clarify the neurobiology of context buildup across sentence boundaries.

Syntactic Processing

A central concern of psycholinguistic models of sentence comprehension is whether the syntactic component of the mental grammar functions as a modular (autonomous) processor without regard for semantic and lexical processes or, instead, is interactively influenced by the activity of those processes. Modular, structure-first models postulate that word category information (e.g., verb, noun, etc.) is used to build an initial phrase structure before integrating the specific argument structure of individual verbs and semantic information into the sentential representation. Constraint-satisfaction models assume parallel real-time interactions among lexical, syntactic, and semantic processes in building an integrated mental representation (McElree and Griffith, 1995).

Recent ERP data support the position that phrase structure is built by an autonomous processor prior to the application of verb argument information. Verbs in correct phrase structures that fail to assign a required thematic role to an NP argument elicit a N400 but no ELAN, reflecting the semantic consequences of an absent thematic role. A phrase structure violation alone or a combined phrase-structure/argument-structure violation elicits an ELAN but no N400, indicating that argument structure cannot be assigned without first building a correct phrase structure (Frisch *et al.*, 2004). While these findings appear to support the modularity of phrase-structure building mechanisms, later syntactic processes may still interact with semantic processes to achieve an integrated mental representation (Friederici, 2002; Hagoort, 2003).

Based on convergent imaging data from ERP and other techniques, Friederici and Kotz (2003) proposed a comprehensive neurocognitive model linking the primary syntactic and semantic ERP components to brain regions. In their model, early and late syntactic processes are associated with separable brain systems lateralized to the left hemisphere. Early syntactic structure building processes reflected in the ELAN are subserved by a temporal-frontal network involving the inferior portion of Broadman area 44 in the inferior frontal gyrus (IFG) and the anterior portion of the

superior temporal gyrus (STG). Late syntactic integration and reanalysis/repair processes are subserved by the basal ganglia and the posterior portion of the STG. Lexical semantic processes associated with the LAN and N400 are subserved by a separate temporal-frontal network involving portions of the STG and IFG. In general, this model entails a functional neuroanatomy of left hemisphere syntactic and semantic processing systems that is substantially domain specific, and is likely to motivate significant future imaging research.

Hagoort (2003) recently proposed an alternative lexicalist account of sentence parsing that challenges the modular structure-first assumption of this model, while still respecting its general domain specificity. Hagoort suggests that syntactic frames associated with each word of the language are stored in the STG and retrieved during on-line sentence processing. IFG mechanisms are responsible for binding these individual frames together in way that respects agreement and subcategorization features.

Reading

Reading is a late-acquired neural process. It recruits posterior visual system mechanisms early in the process to identify printed or written words as abstract visual word forms, that is, as ordered strings of graphemes independent of their physical properties, such as font, size, and location. Restricted areas of the left temporo-occipital cortex provide the initial abstract visual word form used by later word recognition processes to retrieve a word's syntactic, semantic, and phonological features. Recent ERP imaging, coupled with fMRI imaging, have provided concurrent, high-resolution spatial and temporal localization of the visual word form system to the left medial fusiform gyrus, in the time interval of approximately 180 to 200 ms after word presentation (Cohen *et al.*, 2000). The fusiform gyrus is located on the underside of the posterior temporal lobe and is part of the brain's visual object recognition system in the ventral stream.

ERP latency data suggest that lexical access and retrieval of phonological, syntactic, and semantic category information occur subsequent to word-form identification (Dehaene, 1995; Proverbio *et al.*, 2004; Samar and Berent, 1986). ERP studies of the grapheme-to-phoneme conversion processes during reading indicate that the left IFG is strongly activated by orthographically legal pseudowords, whereas the bilateral temporal-occipital and left posterior middle temporal cortex are strongly activated by real words and illegal letter strings (Proverbio and Zani, 2003; Proverbio *et al.*, 2004). This topographic dissociation for different classes of letter strings is consistent with well-known dual route models of reading (Coltheart *et al.*, 1993), which propose that pseudoword reading engages a phonological pathway to assemble a phonological representation based on spelling-sound correspondences and that real word reading engages a lexical-semantic pathway to extract stored phonological representations. Distinct anterior and posterior topographies and separable developmental trends for phonology-sensitive ERP components supports the existence of multiple neural subsystems for different aspects of phonological processing during reading (Grossi *et al.*, 2001).

Little is known about how the initial processing of written words is influenced by different linguistic levels of representation and different writing systems. Limited ERP evidence suggests that prior phonological, lexico-semantic, and sentence-level meaning influence the processing of incoming words during reading (Hoeks *et al.*, 2004; Perfetti *et al.*, 2002). Future dense-array ERP imaging studies will provide rich detail about the neurocognitive architecture underlying both universal and language-specific neural reading mechanisms (Perfetti *et al.*, 2002).

Developmental Language Disorders

Children and adults with developmental language disorders such as specific language impairment and dyslexia display various ERP anomalies (Guttorn *et al.*, 2001; Ors *et al.*, 2002). Generally, ERP studies have helped to confirm that dyslexia, the most common developmental language disorder, is a phenotypically complex impairment of phonological processing, related language processes, rapid auditory temporal processing mechanisms, and transient visual system mechanisms involving wide-ranging brain systems (Stein, 2001). Developmental dyslexics show delayed ERP components for stimuli containing rapid acoustic transitions (Been and Zwarts, 2003; Hugdahl *et al.*, 1998; Ors *et al.*, 2002), show ERP evidence of delayed lexical access (Csepe *et al.*, 2003), and display ERP responses to visual motion stimuli associated with deficits of the dorsal stream, especially of extrastriate visual motion area MT (Schulte-Korne *et al.*, 2004).

Recent studies suggest that ERPs may be useful for the detection of dyslexia in young children and in certain special populations such as the deaf population. Infants with familial risk of dyslexia and infants diagnosed as dyslexic years later display abnormal ERPs to speech stimuli at birth (Molfese, 2000; Guttorn *et al.*, 2001). ERP and psychophysical evidence of dorsal stream dysfunction in deaf adults with exceptionally poor reading skill suggest that ERP imaging may provide a diagnostic marker for hidden

dyslexia in the deaf population that avoids the confounding developmental effects of deafness on reading and English language development (Samar *et al.*, 2002; Samar and Parasnis, in press).

Plasticity of Neural Language Systems

Human language development is a universal cognitive trait whose neurobiology is determined both by innate neurodevelopmental biases and by specific sensory and language experience. ERP studies of healthy and brain-damaged populations exposed to different language forms and language modalities and with different ages of acquisition have helped to identify universal neurobiological systems responsible for higher-order language processing and to determine how specific experiences constrain and optimize the final organization of those systems (Neville and Bavelier, 1998).

ERP studies of deaf and hearing ASL signers and nonsigners have been particularly influential in separating the effects of general sensory experience, language-specific perceptual constraints, and universal linguistic constraints on neural organization. Early ERP components for English words and ASL signs in sentences obtained from native language users show differential topographic patterns for closed class lexical items, which help determine initial syntactic structure during sentence processing, versus open class lexical items, which hold specific semantic content. The ERP patterns implicate anterior brain systems in processing closed class items and posterior brain systems in processing open class items, regardless of language modality (Neville *et al.*, 1997). Hence, the specialization of anterior and posterior systems for grammatical and semantic processing, respectively, appears to be a universal organizational constraint of formal languages. Differential effects on open and closed class words as a function of the age of acquisition of language indicated further that the neural organization of aspects of grammatical and semantic processing may be differentially vulnerable to language delay.

Neville *et al.* (1997) also noted an ERP pattern of more bilateral activation of closed and open class processing systems for ASL signs than for English words, possibly reflecting recruitment of specialized right hemisphere mechanisms for processing language-relevant shape, motion, and location information in ASL, a position supported by recent fMRI data (Newman *et al.*, 2001). Other studies, however, suggest that early signers, but not nonsigners, display a left hemisphere advantage for global motion processing by dorsal stream mechanisms, suggesting that acquisition of ASL may also sometimes drive a left hemisphere lateralization for specialized processing of certain grammatical features of ASL signs (Bavelier *et al.* 2001; Bosworth and Dobkins, 2002; Samar and Parasnis, in press). It is possible that specific grammatical ASL features depend differentially on ventral versus dorsal stream mechanisms or on lower-order versus higher-order visual feature analysis networks within the visual streams, and that the recruitment of these distinct brain systems for language processing requires correspondingly distinct lateralization biases. Future ERP imaging studies of lexical feature processing in ASL may elucidate the specific processing and neural system constraints that drive altered lateralization patterns in the service of sign languages.

Conclusion

Dense-array ERP imaging technology is poised to play an increasingly prominent role, alongside other emerging high-resolution imaging techniques, in comprehensive research programs aimed at understanding the neural organization of language processing systems and the way in which their development is constrained by both genetic endowment and language experience. By extending this technology to various clinical populations, dense-array ERP imaging also has potential as an affordable, noninvasive tool to aid early diagnosis and evaluation of language disorders.

Human speech – the acoustic signal used for language – differs from the sounds produced by our nearest relatives, the great apes. Like apes, humans have a system to convey information about emotional state, using signals such as crying, laughter, and cries of pain or joy. However, humans also use speech to convey complex information. There are two fundamental differences between the primate system and speech. Speech is under voluntary control, whereas the primate system is involuntary. Secondly, the primate system is holistic, whereas speech is combinatorial. A combinatorial system has a small number of basic elements that can be combined into many different sequences. For speech, the basic elements are phonemes or syllables, and these are combined into words and phrases. Holistic utterances do not consist of smaller elements. They cannot be recombined, although they might have some parameters that can be varied, such as pitch and loudness.

Humans have several adaptations to speech. Humans have extraordinarily good control over breathing. Also, the human vocal tract can produce a large number of distinct sounds. In contrast with other mammals, whose vocal tracts are a single tube, the human vocal tract consists of two linked tubes. These are the pharyngeal cavity and the oral cavity, divided by the tongue. This allows a much larger repertoire of possible sounds. As the tongue is important in articulation, and as it needs to move rapidly, it is small compared with those of other primates, and well innervated.

Human hearing is also adapted to speech. Humans are very sensitive to sounds between 1 kHz and 4 kHz. This is approximately the range of the resonance frequencies of the human vocal tract that determine the timbre of speech sounds.

Humans also have neurological adaptations to speech. They are good at performing rapid controlled and coordinated movements with both their

Human speech – the acoustic signal used for language – differs from the sounds produced by our nearest relatives, the great apes. Like apes, humans have a system to convey information about emotional state, using signals such as crying, laughter, and cries of pain or joy. However, humans also use speech to convey complex information. There are two fundamental differences between the primate system and speech. Speech is under voluntary control, whereas the primate system is involuntary. Secondly, the primate system is holistic, whereas speech is combinatorial. A combinatorial system has a small number of basic elements that can be combined into many different sequences. For speech, the basic elements are phonemes or syllables, and these are combined into words and phrases. Holistic utterances do not consist of smaller elements. They cannot be recombined, although they might have some parameters that can be varied, such as pitch and loudness.

Humans have several adaptations to speech. Humans have extraordinarily good control over breathing. Also, the human vocal tract can produce a large number of distinct sounds. In contrast with other mammals, whose vocal tracts are a single tube, the human vocal tract consists of two linked tubes. These are the pharyngeal cavity and the oral cavity, divided by the tongue. This allows a much larger repertoire of possible sounds. As the tongue is important in articulation, and as it needs to move rapidly, it is small compared with those of other primates, and well innervated.

Human hearing is also adapted to speech. Humans are very sensitive to sounds between 1 kHz and 4 kHz. This is approximately the range of the resonance frequencies of the human vocal tract that determine the timbre of speech sounds.

Humans also have neurological adaptations to speech. They are good at performing rapid controlled and coordinated movements with both their

hands and their articulatory organs. Humans are much better at this than other primates. Interestingly, rapid hand movements are also used in human sign language.

All these properties must be explained by evolution. The next sections provide background information on the evidence for the evolution of speech, and a sample evolutionary scenario.

Fossil Evidence

The shape of the human vocal tract must have changed during evolution. Unfortunately, because it is determined mostly by soft tissue, scientists have been unable to reconstruct its evolution from the fossils that have been found so far. However, better control of breathing and tongue movement are also adaptations to speech. As larger nerves are needed for better control, researchers have investigated the holes in the skull and vertebrae through which these nerves pass.

Kay *et al.* (1998) investigated the size of the hypoglossal canal, through which the main nerve of the tongue passes. They determined that it is relatively larger in humans than in chimpanzees and gorillas. When comparing different fossils, they found that the canals in modern and early *Homo sapiens* and in Neanderthals were similar in size to the human canal, while those in *Australopithecines* and *Homo habilis* were chimpanzee-like. They concluded that 'human vocal abilities' existed 400 000 years ago.

MacLarnon and Hewitt (1999) studied the thoracic vertebral canal, through which the nerve controlling the diaphragm, and therefore breathing, passes. They found that it is significantly larger in humans than in apes and that Neanderthals and early *Homo sapiens* fell in the modern human range, while *Homo ergaster* and the Australopithecines did not. They estimated that increased breathing control emerged between 1.6 million and 100 000 years ago.

With regard to the perception of speech, Martínez and colleagues (2004) calculated the frequency sensitivity of *Homo heidelbergensis*, whose fossils are about 350 000 years old. They found that the frequency sensitivity in the range of speech was like that of humans. This contrasts with chimpanzees, which have quite different frequency sensitivity.

This evidence suggests that adaptations for speech first appeared in the common ancestor of *Homo sapiens* and *Homo neanderthalensis*. Early work by Lieberman and Crelin (1971), however, suggested that the Neanderthal vocal tract was not a two-tube system. This used to be interpreted as an argument against Neanderthal speech, but more recently Lieberman has accepted the possibility of speech in Neanderthals.

Parallels in Other Animals

To know the starting point of the evolution of speech, it is necessary to investigate primate vocal abilities. There are animals other than primates that use complex vocal communication that is combinatorial and learned. Examples of these are songbirds and humpback whales. As these species are quite distant evolutionary, this must be parallel evolution. It is interesting, however, to compare these animals with related species with fewer vocal abilities. Fitch (2000) reviewed animal vocalizations in the context of evolution of speech.

Primates do use vocal communication extensively, but their vocalizations are like human emotional utterances. Research cited by Hauser (1997) indicated that primate vocalizations are mostly innate but that details might be learned. He also indicated that "no convincing demonstration" of vocal imitation existed, except in captive chimpanzees and orangutans. Attempts to teach orangutans or chimpanzees to speak have failed, in contrast with attempts to teach apes sign language. This is understandable, as apes have different vocal tracts and less accurate motor control. However, the attempts do show that these animals have some voluntary control over vocalization. As for perception, apes can understand speech to some degree, and therefore must be able to perceive some of the acoustic distinctions of speech.

Little is known about the structure of ape calls and its relation to human phonology. The long calls of gibbon species are perhaps best studied; these have compositional structure, in that smaller units are recombined into novel utterances (Mitani and Marler, 1989). Among the apes, gibbons are most distantly related to humans. All other apes have simpler calls; therefore, gibbon calls cannot be direct precursors of speech. Nevertheless, they show that apes can handle the complexity of producing and processing combinatorial calls.

There is considerable anatomical overlap between brain organization of vocalizations in primates and speech humans. According to Ploog (2002), two pathways exist in both humans and other primates: the 'cingulate vocalization pathway' for the emotional content of speech, and the 'neocortical vocal pathway' for fine motor control. The latter is more developed in species closer to humans.

Mechanisms

The observations mentioned thus far in this article show that (proto-) humans had adaptations for

modern speech at least 400 000 years ago, while the last common ancestor of chimpanzees and humans had preadaptations for speech. It had fewer articulatory possibilities, and insufficient control of articulation and breathing. It probably also could only imitate and learn utterances on a very limited scale. This was the starting point of the evolution of speech.

Modern speech gives an idea of what abilities have evolved. Maddieson (1984) and Ladefoged and Maddieson (1996) gave an overview of the possible speech sounds (and syllables). These can be extremely complex, but it is also useful to know that there are languages with very simple sound systems. The simplest one is Piraha, which uses only 11 phonemes, while Hawaiian is one of the languages with the smallest number of syllables: 162 (Maddieson, 1984). It is also sometimes said that modern language is impossible without the vowels /i/, /a/, and /u/. However, there are languages with vertical vowel systems that do not have /i/ and /u/. Hugely complex speech is unnecessary for modern language.

For a theory about evolution of speech, several mechanisms must be considered. Speech is a learned system in a population, and therefore cultural evolution is important. Genetic changes that allow an individual to use signals that cannot be used by other individuals are useless. Therefore, cultural evolution must drive genetic evolution. Innovations in speech spread culturally, after which genetic adaptation to these innovations becomes useful. This is the so-called Baldwin effect.

The physical nature of speech also causes functional pressures to play a role in its evolution. Not all properties of speech need to be explained as the result of adaptations of the brain. Several researchers have proposed functional pressures to explain properties of speech (for an overview, see Chap. 2 of de Boer, 2001). These are acoustic distinctiveness, articulatory ease, and articulatory stability, among others. Through self-organization in a population, functional pressures can determine what sounds will be used in speech.

Another mechanism is exaptation. Evolution tends to adapt existing systems for new functions. Anatomical parallels between primates and humans show that many parts of the primate brain associated with vocalization and motor control and with acoustic perception have been exapted for speech. But behaviors can be exapted as well. MacNeilage and Davis (2000) proposed that oscillatory jaw movements, such as chewing, form the basis of the syllable structure of speech.

The theory that speech evolved from sign language is also an example of exaptation. Although it is remarkable that language can be expressed with both gestures and sounds, the theory does not explain how and why sign language has evolved into spoken language.

A Possible Scenario

So far, facts have been presented here that are pertinent to the evolution of speech: fossil evidence, knowledge about our evolutionary relatives, and knowledge of the evolutionary process. Any attempt to build a scenario of the evolution of speech must, however, be speculative. Such a scenario is nevertheless useful to illustrate how different pieces of evidence can fit together, but it must be seen as just a possibility. Researchers do not agree on a definitive scenario.

Evolution of speech must have started with the ability to learn novel utterances, allowing a culturally transmitted sound repertoire to emerge. This ability could have been exapted from tool use. The repertoire could initially also have contained gestures. As primates prefer vocal communication, the burden in a hybrid system would have shifted to vocal communication. Having to learn new utterances made it necessary for the utterances to be more distinctive, thus putting pressure on breathing control, motor control, and vocal tract shape. At this point, anatomical adaptations would have appeared. As the repertoire expanded, it became more difficult to learn all utterances; hence, combinatorial structure would have become advantageous. Adaptations facilitating the use of this structure would have been an advantage, although at first the utterances could still have been learned without them. Later, both cognitive abilities and linguistic complexity would have increased, until being able to handle combinatorial structure became essential. Speech at this stage had all the essential characteristics of modern speech, although the repertoire of speech sounds was probably much smaller.

Through functional pressure and self-organization, sound systems would have acquired certain universal characteristics. Some sounds and combinations of sounds would have occurred more often than others. Neural adaptations to these universals probably occurred. As a result, early combinatorial speech evolved into complex modern speech, with all its phonological rules.

Fossil evidence shows that early *Homo sapiens* must have used complex articulations, whereas *Homo erectus* probably did not. Whether these articulations were combinatorial remains an open question, but as gibbons (with much smaller brains) use combinatorial calls, it is likely that early *Homo sapiens* also used combinatorial speech. The repertoires of sounds might not have been very complex. However, given

that there exist modern languages with simple sound systems, the evolution of speech provides no reason that early *Homo sapiens* did not have complex communication.

Introduction

Imagine you are walking through a forest. You approach a clearing in the middle of which you notice three tall sticks standing in the ground. Are they young saplings? No, as you get closer you notice that each stick has been stripped of its bark, that one end of each has been sharpened, and that all three have been forcibly embedded into the ground. This is no natural occurrence; someone has put the sticks there deliberately. You begin to wonder. The sticks are arranged in a straight line each about a meter apart, but the two outer ones are angled inwards, so it's unlikely they're intended as a fence. They are not hidden, so it is unlikely that someone has left them there to collect later. Since they have been put there deliberately, however, they must have been put there for a reason: why?

This is the kind of question we humans ask a lot. We strive to interpret the actions or behavior of others in terms of the reasons or intentions that might have led them to act or behave in the way they did. In the above scenario, our natural disposition is to try and work out (infer) the intentions behind the action of placing the sticks where they were. Despite the absence of the person who placed the sticks in the ground, you can't help wondering what he or she might have meant by putting them there.

Pragmatists have noticed that this disposition also comes into play when the behavior in question is linguistic. After all, there is much more to understanding the full message that a speaker is trying to convey than simply knowing the meaning of the words themselves. Consider example (1) below:

(1) Jack: Are you going to Bill's party?
Lily: Bill doesn't like linguists.

The words Lily utters in response to Jack's question have stable, context-independent meaning: linguistic meaning. Jack knows the linguistic meaning of Lily's utterance because he can speak English. The study of this level of meaning is linguistic semantics. But what about the full message Lily intends to convey with her reply – her 'speaker meaning'? This message need not be closely tied to the words she utters at all; it is context-dependent as opposed to context-independent. If I tell you that Lily is a linguist, and that Jack knows this, then the message she intends to convey might be that she will not be going to Bill's party. This level of meaning – what speakers, as opposed to words mean – is the domain of pragmatics.

Of course, pragmatics is many things to many people: there are over 100 entries in the 'pragmatics' section of this encyclopedia and a quick flick through

that there exist modern languages with simple sound systems, the evolution of speech provides no reason that early *Homo sapiens* did not have complex communication.

Introduction

Imagine you are walking through a forest. You approach a clearing in the middle of which you notice three tall sticks standing in the ground. Are they young saplings? No, as you get closer you notice that each stick has been stripped of its bark, that one end of each has been sharpened, and that all three have been forcibly embedded into the ground. This is no natural occurrence; someone has put the sticks there deliberately. You begin to wonder. The sticks are arranged in a straight line each about a meter apart, but the two outer ones are angled inwards, so it's unlikely they're intended as a fence. They are not hidden, so it is unlikely that someone has left them there to collect later. Since they have been put there deliberately, however, they must have been put there for a reason: why?

This is the kind of question we humans ask a lot. We strive to interpret the actions or behavior of others in terms of the reasons or intentions that might have led them to act or behave in the way they did. In the above scenario, our natural disposition is to try and work out (infer) the intentions behind the action of placing the sticks where they were. Despite the absence of the person who placed the sticks in the ground, you can't help wondering what he or she might have meant by putting them there.

Pragmatists have noticed that this disposition also comes into play when the behavior in question is linguistic. After all, there is much more to understanding the full message that a speaker is trying to convey than simply knowing the meaning of the words themselves. Consider example (1) below:

(1) Jack: Are you going to Bill's party?
Lily: Bill doesn't like linguists.

The words Lily utters in response to Jack's question have stable, context-independent meaning: linguistic meaning. Jack knows the linguistic meaning of Lily's utterance because he can speak English. The study of this level of meaning is linguistic semantics. But what about the full message Lily intends to convey with her reply – her 'speaker meaning'? This message need not be closely tied to the words she utters at all; it is context-dependent as opposed to context-independent. If I tell you that Lily is a linguist, and that Jack knows this, then the message she intends to convey might be that she will not be going to Bill's party. This level of meaning – what speakers, as opposed to words mean – is the domain of pragmatics.

Of course, pragmatics is many things to many people: there are over 100 entries in the 'pragmatics' section of this encyclopedia and a quick flick through

them reveals modern pragmatics to be made up of a wide range of subdisciplines. There's conversational analysis, the pragmatics of gesture and gender, literary pragmatics and historical pragmatics to name only a few. Indeed, one way of looking at the evolution of pragmatics would be to interpret it as concerning the development of the discipline of pragmatics and to trace its historical development from the writings of Charles Morris and, in the case of English pragmatics, the literature in ordinary language philosophy at Oxford in the 1940s and 1950s (Austin, 1962; Grice, 1989).

The sense of the word 'evolution' used in the title of this essay, however, is the biological one. So for talk of the evolution of pragmatics to make any sense at all, we need to adopt a view of pragmatics that somehow ties it in with biology, and more generally with the 'natural' world. One way to do so is to adopt a cognitive viewpoint and regard pragmatics as – ultimately at least – a branch of cognitive science or psychology. Such a view owes a lot to the work of Noam Chomsky (2000), who advocates a similar, 'naturalistic' view of language (*see* **Naturalism**). Construed in this way, pragmatics is not just an academic enterprise, it is:

> a capacity of mind . . . a system for interpreting a particular phenomenon in the world, namely human ostensive communicative behavior. (Carston, 2002: 4)

This essay, then, concerns itself with how the capacity of mind that is pragmatics evolved. It is not an essay about the evolution of language (*see* **Origin and Evolution of Language**). The human pragmatic capacity is implicated in the interpretation of all kinds of human communicative behavior: true, that behavior may well – and perhaps most often does – consist in uttering a string of words (accompanied perhaps by a nonverbal behavior such as a gesture or a facial expression), but it could just as easily consist in planting some sticks deliberately into the ground.

The section 'The Pragmatic Capacity' looks briefly at how human communication works, and articulates what the human pragmatic capacity is. This section involves an exploration of what identifies human behavior as 'ostensive' and 'communicative' (the kind of behavior the capacity has evolved to interpret). It also looks at the foundational cognitive machinery the capacity appears to be built upon. The section 'Metarepresentation and Evolution' examines some of the broader questions an evolutionary account needs to address. To what extent is the evolution of this foundational machinery bound up with the evolution of communication? What circumstances might have led to the evolution of such mechanisms, and how did they become a specialized pragmatic capacity? Bearing the answers to these questions in mind, the section 'The Evolution of Pragmatics' presents one version – in the form of a step-by-step account – of the evolution of pragmatics. This progression is based on a 'myth' originally offered in Grice (1982) but in what follows is independently endorsed by research into the evolution of human cognition.

The Pragmatic Capacity

Ostensive Behavior

Whichever of the subdisciplines of pragmatics you choose to focus on, there is a good chance it will owe at least something to the work of H. Paul Grice. Grice (1989) was a philosopher who wrote some highly influential papers and delivered the William James Lectures – called 'Logic and Conversation' – in 1967, out of which modern pragmatics developed.

Part of Grice's legacy is that our view of how humans communicate has changed completely. According to the traditional 'code model' of communication – which dates back to Aristotle – a communicator's thoughts are translated into a signal by the use of a code (in this case, language), and translated back from the signal by an audience into the original message. Post Grice, human communication has come to be regarded as an intelligent, intention-driven, inferential activity (*see* **Inference: Abduction, Induction, Deduction**). Rather than simply being a process of coding and decoding, human communication is achieved by a speaker giving evidence of an intention to inform the hearer of something, and the hearer inferring a conclusion from this evidence.

Consider the following example. If a colleague catches your eye at a meeting and looks in a deliberate manner towards the door (perhaps accompanied by a mimed yawn), then you might infer that your colleague is bored and wants to leave. But this communication is not achieved by coding and decoding. Rather, what the behavior made clear was the fact that your colleague had an intention to inform you of something: communication was achieved by your inferring what this was, rather than decoding your colleague's actions.

Of course, to adopt this view of communication is not to deny the role of coding and decoding in the special case of linguistic communication. In order for Jack to derive Lily's intended meaning in (1), he does indeed need to know the linguistic meaning of the sentence that Lily utters. Crucially, however, he only needs to know it because it provides him with a clue to the speaker meaning that she intends to convey. Her utterance makes clear that she intends to

communicate something to him, and he has to infer what the content of this intention is.

There have been various proposals as to how this inference is made. A common story (initially proposed by Grice) has it that Jack begins from the presumption that Lily is being cooperative in her response (perhaps by following a 'cooperative principle' and 'maxims'), or 'relevant' in some sense of the word (*see* **Relevance Theory** – Sperber and Wilson, 1986/1995). Jack uses this presumption to construct the best available hypotheses about Lily's intended meaning. Since Jack has asked her a question, he obviously expects an answer, and Lily would be being neither cooperative nor relevant if her only intention was to communicate to Jack that Bill doesn't like linguists. Jack knows, however, that Lily is a linguist, and based on the presumption that Lily is cooperating (or that she believes it is relevant to tell him that Bill doesn't like linguists), Jack can infer that Lily's intention is to communicate that she will not be going to Bill's party. Whatever story you decide to tell, as well as possessing the requisite semantic competence, in order to interpret speaker meaning, hearers must possess something more, and use this information to work out what was meant.

This 'something more' involves a range of factors. Since it involves inferring the intentions of others, it presupposes an awareness that other people have intentions in the first place. This observation is not a trivial one: other people's intentions and mental states generally are not objects to be perceived in the world in the same way as are their faces or bodies; they are 'out there,' but they are invisible. Equally, it presupposes the existence of mechanisms by which these hypotheses about the intentions of others can be represented: a 'framework,' if you like, on which representations of the thoughts and intentions of others can be hung. Finally, it presupposes the existence of standards or expectations about proper communicative behavior according to which hearers form the best hypothesis about a speaker's intended meaning.

On the last of these points, I will have little to say; not because the existence of such standards or expectations is not linked to the evolution of pragmatics, but because the attempt here is to tell a much more general story. Suffice to say, humans are rational beings, and successful communication (in general) proceeds along rational lines according to such standards or expectations. In what follows, I will be interested in the extent to which human communication involves the expression and attribution of intentions (and what kinds of intentions are expressed and attributed), and the mechanisms that underlie our ability to do this.

So, what kinds of intentions are involved? A first suggestion might be that all that is required for an act to be 'ostensive' or 'communicative' is that the agent of the act has an intention to impart some information to an audience. A moment's reflection, however, reveals that having this intention is not enough. If I intend to inform you that I want a particular book for my birthday, I might decide to leave a magazine casually open at the page where I have ringed a review of the book in question with a pen. Notice that in this scenario, I don't want you to know that leaving the magazine for you is my intention: I leave the magazine looking as if it has fallen open at this page naturally.

Many people (including Grice) see a sense in which this kind of example is problematic; those who do see the problem as residing in the fact that there is something covert about the way I have behaved. Indeed, there is a sense in which the kind of transfer of information in this example doesn't even count as 'communication,' which – after all – we feel to be a joint activity. In any case, even if we do regard this situation as an instance of communication, it is certainly not the kind of communication that is reliant in any way on the expression and attribution of intentions. It can't be, since you are unaware I have an intention to inform you of anything. In this example, my behavior is not 'ostensive.'

For an act or behavior to count as ostensive, we need another intention. This one is the 'higher-order' intention that the intention to impart some information be revealed. So in the above example, I would not only need to intend to inform you that I would like the book for my birthday, but also intend you to **realize** that this is my intention. I could achieve this higher-order intention in a variety of different ways. One way would be to make it obvious to you that I have left the magazine open deliberately: I might leave it out in a highly prominent position – perhaps open on your desk; another would be to write 'Birthday present please!' next to the circle I have drawn around the review; still another would be to point out to you the fact that I have circled the review as you enter the room. In keeping with the terminology adopted by Carston in the above quote, I call behavior with this kind of higher-level intention 'ostensive communicative behavior.'

Returning to the example in my opening paragraph, one reason that the three sticks deliberately stuck in the ground attract your attention so is that they may be evidence to you that someone has the higher-order intention that you realize that they have a basic intention to impart some information to you. Having recognized the higher-level intention, you are

naturally predisposed to try and infer what this basic intention is.

Theory of Mind

The capacity to infer this kind of complex intention is closely related to – perhaps even a part of – the human ability to attribute mental states in general, including beliefs, intentions, and desires: the ability widely known as 'mind-reading' or 'theory of mind' (Baron-Cohen, 1995). Imagine two people running past you quickly down a road, one behind the other: A, the person behind, is gesticulating angrily; B, the person in front, is looking over his shoulder with a certain expression of fear. Rather than viewing their motion as you might view the random motion of two billiard balls – one apparently 'following' the other around a billiard table – it is an automatic response to interpret their behavior in terms of the mental states that underlie it. At a basic level, you would perceive their actions in terms of their goals and desires; in terms of the person behind – A – wanting to catch the second – B, or B's desire to escape.

However, as well as these basic concepts, you would also attribute to A and B more complex mental states (Leslie, 1994). So, for example, it might be clear to you that A **believes** that B has done something wrong (the complex mental state underlying A's goal), and that B believes that A **intends** to catch him (the complex mental state underlying B's desire to get away). Notice that the kind of beliefs you attribute may well be incompatible with the beliefs you yourself hold: you have no problem attributing to A the belief that B has stolen his wallet, even though you know that B has not (because, for example, you have A's wallet in your pocket).

Since the ability underlying theory of mind is recursive, our own and others' mental states can be represented in a multilayered way, to a number of different levels. Watching the chase, you have no problem entertaining the thought that B believes that A believes that he has done something wrong, or even that A believes that B believes that A believes that he has done something wrong (or even, for that matter, that B believes that A believes that B believes that A believes that he has done something wrong, etc.). The mind-reading ability – and, therefore, the pragmatic capacity – is underpinned by a more general ability that humans have to represent other representations, or, to use another current piece of terminology, to 'metarepresent.' The pragmatic capacity is built upon this ability.

The kind of representations humans might metarepresent can be either public ones – such as the linguistic utterance in example (2), or mental – such as the thought in example (3). The pragmatic capacity must at the very least involve the ability to entertain and manipulate metarepresentations as complex as the one(s) in (3) (where the metarepresentation is the emboldened part):

(2) Lily said **that Bill doesn't like linguists.**

(3) Lily intends **me to realize that she intends to inform me that she isn't going to Bill's party.**

Developmental psychologists have designed experiments to discover at what age this ability emerges in humans (by about four years old), and have shown that it is subject to pathological breakdown. Autistic individuals, for example, typically fail tests in which they have to explicitly attribute to others beliefs incompatible with their own, and this inability is generally taken to be evidence that they lack full-blown theory of mind (Leslie and Happé, 1989; Happé, 1994; *see* **Autism and Asperger Syndrome: A Spectrum of Disability**). While some autistic individuals acquire language, the condition is typified by an inability to communicate anywhere near 'normally': those who **do** understand words find it hugely problematic, sometimes impossible, to understand what speakers mean by them.

Metarepresentation and Evolution

Over recent years, there has been a tremendous amount of research into the human mind and the evolution of human cognition. In particular, people have questioned the long-held view that humans are endowed with general, all-purpose cognitive abilities, which they bring to bear on any cognitive task set before them. Philosophers of mind (Fodor, 1983) have argued that the mind (or part of it) is modular: that it is an organized system of individual, highly specialized mechanisms (*see* **Modularity of Mind and Language**). The existence of conditions such as autism lends support to this proposal. Cognitive scientists and evolutionary psychologists argue that these domain-specific mechanisms have evolved as adaptations to deal with specific challenges in the ancestral hominid environment (Hirschfeld and Gelman, 1994). The mind, viewed in this way, is an 'adaptive toolbox.'

We are now in a position to begin asking evolutionary questions, such as those I posed in the introduction. Indeed, since the pragmatic capacity is some kind of specialized metarepresentational ability, we can be more specific in the kind of questions we ask. Before we look at possible scenarios in the evolution of the pragmatic capacity, we need to look at the evolution of the metarepresentational ability.

All nonhuman animals with cognitive capacities possess the ability to represent, but the ability to

entertain representations of representations – and representations of representations of representations, etc., – appears to be as unique to humans as the ability to use echolocation is unique to bats (Sperber, 2000b: 117). Indeed it has even been suggested that the sophistication of the human metarepresentational ability underlies our ability to be aware of our own thoughts, and is therefore implicated in one of the biggest mysteries of all: human consciousness.

A striking feature of much of this work is that while there is disagreement on the factors that may have led to the evolution of such an ability, there is broad agreement at least that it could have evolved – or at least begun to evolve – independently of communication. One view (Cosmides and Tooby, 2000) proposes that the ability to 'detach' ourselves – mentally, at least – from the here-and-now, and entertain a representation of a situation as something other than a true belief about the world, would have improved our adeptness in reacting and responding to local aspects of the environment. This ability would have enabled humans to adapt to the environment spontaneously – for example, by making plans – rather than having to adapt (as does the rest of the animal kingdom) on an evolutionary time-scale. Such improvisational skills would have proved highly adaptive.

Another view – The Machiavellian Intelligence Hypothesis (Byrne and Whiten, 1988) – suggests that as well as the task of interacting with the natural environment, a particular challenge for humans (and, indeed, primates generally) was the task of dealing with the complexity of social interaction. In the human case, it is proposed that this challenge led to a kind of 'Cognitive Arms Race,' within which human cognitive abilities spiraled – mainly in order to help individuals compete with their conspecifics and perhaps outmaneuver them. The ability to interpret behavior in terms of the motives behind it would have given an individual strong predictive powers, and it would have been adaptive to become more and more adept at working out the thoughts and feelings of others (Humphrey, 1984).

A recent paper (Tomasello *et al.*, in press), points out that as well as evolving the ability to compete and deceive, humans also evolved the ability to collaborate and cooperate. This unique human disposition to share intentions – in which a metarepresentational ability is also implicated – may form the foundations upon which much human interaction (and possibly human culture) is built.

Of course, sensing how someone else is feeling does not necessarily require complex metarepresentational abilities. Well before full-blown human theory of mind develops, a young infant can sense the emotional state of its carer. Indeed, a great deal of the way humans sense the emotional states of others is done in other – nonintentional – ways. Consider the automatic way in which we interpret facial expressions, or the way panic spreads through a crowd. The cries that alert others to danger in this situation may not be uttered with intentions, and are on the whole not understood by attributing intentions. Presumably at some early stage in our evolution, this was how we were able to sense whether or not people were friendly or a threat, or whether a situation was safe or dangerous.

Before the evolution of metarepresentation, our ancestors were 'ignorant of an inner explanation for their own behavior' (Humphrey, 1984: 49). But once they were selected, rudimentary metarepresentational abilities could have spiraled and spiraled until they eventually led to the evolution of the kind of complex mechanisms that underlie full-blown theory of mind. Tooby and Cosmides (1995: xvii) put it like this:

> Unobservable entities . . . are 'visible' to natural selection . . . Over innumerable generations, the evolutionary process selected for modules . . . that could successfully isolate, out of the welter of observable phenomena, exactly those outward and visible signs in behavior that reliably signaled inward and invisible mental states.

At a crucial evolutionary stage, then, humans somehow became aware that they were living not just in a world populated by other faces and instinctive cries, but a world populated by other minds.

There is little evidence so far that nonhuman animals possess mind-reading abilities to anything like the degree of sophistication found in humans (Premack and Premack, 1983; Hauser, 1996) and hence recognize that their signals **mean** anything. In many ways, this lack of evidence could be seen as presenting problems for an evolutionary account of, for example, theory of mind (Plotkin, 1997). Our common ancestor with the chimpanzee (who lived about 7 million years ago) may have possessed imitative capacities, and these may have been refined into metarepresentational abilities along the hominid line since then, but there is scant evidence among modern-day chimpanzees that they possess anything other than the most rudimentary metarepresentational abilities. The communicative skills of chimps are very basic; indeed, even the more sophisticated nonhuman animal communication systems work along entirely different lines to human communication.

Consider vervet monkeys: when a vervet sees a predator, it emits a specific alarm call (*see* **Alarm Calls**) that alerts other monkeys in the group: a loud barking call for leopards; a short, double-syllable cough for eagles; and a 'chutter' sound for snakes (Cheney and Seyfarth, 1981). However, on hearing a

vervet monkey produce an alarm call, a vervet need not presume that the calling vervet is being cooperative or relevant in order to work out precisely what it means. Vervet monkeys don't mislead, and they don't answer questions indirectly. Communication is achieved without either the sending or receiving animal consciously recognizing that the signal means anything. Indeed, studies suggest that the vervet has very little control over the production of the call itself; it is more as if vervets exploit a reliable correlation between hearing an alarm call and there being a predator in the vicinity rather than that there is any 'meeting-of-minds.' What we need to show is why, and how, human communication evolved along such radically different lines.

The Evolution of Pragmatics

To recap: the human pragmatic capacity is "a system for interpreting ... human ostensive communicative behavior." Ostensive behavior is behavior that reveals a certain complex type of intention, and so the pragmatic capacity is a system that makes the recognition and attribution of such intentions possible. In other words, it is a specialized version of the human ability to attribute mental states.

To what extent would it need to be a specialized version of this ability? There are a number of issues to bear in mind. First, the types of 'meaning' that a speaker can convey by producing an utterance are generally much more complex than the types of intention normally attributed to someone in order to explain their observed behavior. Second (and related to the first), we often attribute intentions to others by observing the effects of their actions, deciding which of those effects they might have desired, and attributing to them the intention to achieve those desired effects: the 'chase' between A and B is a good example. However, a speaker will achieve very few effects by producing an utterance unless she is first understood, so the normal procedures for recognizing the intentions behind ordinary noncommunicative actions won't work: the hearer can't first observe the effect of an utterance and then infer what it meant.

Thirdly, in order to understand intentional communication – as opposed to ordinary noncommunicative behavior – it is necessary to be able to attribute several layers of metarepresentations; yet young children below the age of four – the same children who (as do autistic subjects) fail standard theory of mind tests – master verbal communication quickly and effortlessly well before this age. Based on these and other arguments, Sperber and Wilson (2002) propose that the theory of mind inferences central to the interpretive process are performed by a domain-specific 'comprehension' mechanism or module. This comprehension module is an evolved submodule of the theory of mind module: another part of the human 'adaptive toolbox.'

Consider the following scenarios, which are intended to be seen as taking place over many, many generations. Imagine a tribe of our hominid ancestors. When these ancestors are tired, they involuntarily yawn. To other hominids, a yawn reliably correlates with tiredness in the same way that, say, black clouds correlate with rain (or – though there are differences – the vervet alarm call correlates with the presence of a predator). Crucially, though, a metarepresentational ability is already evolving along the hominid line: perhaps to help better exploit the environment; perhaps to facilitate more complex social interaction. Our ancestors already have rudimentary metarepresentational abilities, and the evolution of the pragmatic capacity should be seen against the backdrop of this independently-evolving metarepresentational prowess.

In the first scenario, one member of the tribe – call him Jack – is able to fake a yawn. Another member – call her Lily – recognizes the voluntary, unspontaneous nature of Jack's yawn. At this stage, the fact that Lily recognizes that Jack has faked the behavior may lead her to come to the conclusion that he is not tired. Jack is producing a normally involuntary behavior voluntarily and could, after all, be trying to deceive her.

Now, let's move to scenario two. In this scenario, we imagine that not only does Lily recognize that Jack has faked a yawn, but also that Jack intends Lily to recognize his behavior as such. Jack and Lily can already metarepresent in a rudimentary way: the metarepresentational ability, recall, is evolving independently. He is 'aware' of his intention, and is metarepresenting its content – as in (4) – and she is entertaining the metarepresentation in (5) below:

(4) I intend **that Lily recognizes my intention to fake this yawn.**

(5) Jack intends **that I recognize that he intends to fake a yawn.**

The possibility of deception – a plausible interpretation in the previous stage – is no longer the only possibility. Of course, Lily is still likely to be in something of a quandary. Jack is not only apparently faking a yawn, but also doing so overtly. It does not seem unreasonable to suggest that one way Lily might proceed is to presume that Jack is pretending or being playful. By the time such a conclusion is arrived at by Lily, we have reached a third scenario.

Consider now a fourth scenario. Lily has come to suppose not that Jack is playing a game, but rather that Jack is trying to get Lily to believe (or at least accept) that he is, in fact, tired. That is, that Jack's intention in producing the normally involuntary behavior voluntarily is to communicate the very same thing the involuntary behavior normally conveys. By this stage, of course, Lily may wonder precisely why Jack should choose to use a faked yawn to communicate tiredness as opposed to an involuntary one. There may be various reasons; one reason may be that Jack's voluntary production might only be intended to indicate some, as opposed to all, of the features associated with an involuntary yawn. Perhaps Jack is tired, but not so tired as to yawn involuntarily; perhaps he is feeling drowsy because he feels unwell. Recall the example described in the section 'The Pragmatic Capacity,' where a faked yawn is used to communicate boredom. Whatever he intends to inform Lily, he is – at this stage – entertaining the metarepresentation in (6):

(6) I intend **Lily to realize that I intend to inform her that** . . .

And Lily, if she recognizes his intention, is entertaining the metarepresentation in (7):

(7) Jack intends **that I realize that he intends to inform me that** . . .

By the time we have reached this scenario, Jack's behavior is 'ostensive' in the sense defined earlier, and Lily has engaged in the kind of pragmatic inference modern-day humans employ. If such a system of communication can be shown to have been advantageous, we can imagine that the cognitive abilities necessary to engage in such communication would have been selected for.

What might the advantages be? Why should already-evolving metarepresentational abilities be recruited – or 'exapted' (Gould, 1980) – for use in communication? The main advantage is that it is the intention behind the behavior, rather than the behavior itself, which plays the main role in Lily's successful understanding of Jack. Communicators have reached a stage where the ostensive behavior need have nothing more than a very tenuous connection with the message a communicator intends to convey, so long as the communicator thinks the audience can infer it. In short, hominids have gone from only being able to communicate by exploiting 'natural' correlations and being able to communicate only a limited number of things, to also being able to communicate non-naturally (*see* **Natural versus Non-natural Meaning**), employing systems of representations, and being able to communicate virtually anything at all.

Of course, communication along these lines would at first have been slow and effort-consuming. The limitless possibilities such a system would have opened up, though, would have given humans an enormous advantage that presumably came to outweigh the costs. If we imagine scenarios such as these taking place generation after generation, and consider them against the back-drop of the developing metarepresentational ability, we have a plausible account of how ostensive communicative behavior and – moreover – the specialized cognitive mechanisms required to interpret such behavior could have evolved. Over evolutionary time, slow, conscious reasoning processes would have come to be replaced by 'fast and frugal heuristics' (Gigerenzer and Todd, 1999) which made this kind of pragmatic inference automatic. In modern humans, they are carried out by a dedicated submodule of theory of mind: the pragmatic capacity.

Now Jack is walking through a forest. As he approaches a clearing, he hears an animal cry. In the middle of the clearing, he sees a large rodent disappearing slowly into a wide pool of quicksand. He becomes tense. His tribe uses this route frequently, and even if he shouts at the top of his voice, he knows they will not be able to hear him from here. He thinks. He has to go on, but he must warn his people. If he places a log in front of the quicksand, there is a chance that some people will walk around the log and hence successfully avoid the quicksand. Many, however, will simply presume that the log has fallen naturally and step straight over it into danger. He thinks again. He walks over to a small tree and cuts off three long, thin branches. He strips off the bark and starts to sharpen them.

One of the most important functions of language is to facilitate the 'transmission' of thought from one language user to another. A number of scholars, including Sperber and Wilson (1995), and Tomasello (1999, 2003), have observed that verbal communication requires both a code – which is to say a language-system involving conventional symbols, pairings of form and meaning – and intentional mechanisms such as inference-reading abilities. While both these aspects are essential for verbal communication, communication can, in principle, occur in the absence of a code. Indeed, as we shall see, intentionality and the ability to recognize communicative intentions are likely to have been necessary prerequisites for the evolution of symbolic representation in language.

To function as a means of communication, an important prerequisite of a code, which is to say a language-system, is to be able to encode and externalize humanly-relevant concepts and combinations of concepts. Semantic knowledge, therefore, concerns the range and nature of humanly relevant concepts that can be expressed in language, and the way language serves to combine concepts in order to convey complex ideas. In this article, we explore (i) possible cognitive preadaptations for the development of semantic knowledge, and (ii) the range and nature of conceptual structure as encoded in language, and suggestions as to the way that this structure may have evolved.

Unlike some other aspects of language, there is scant evidence we can draw on in attempting to reconstruct the evolution of semantic knowledge. After all, we are, in essence, attempting to reconstruct the evolution of human cognition. To do this, we are

Evolution of Semantics

V Evans, University of Sussex, Brighton, UK

One of the most important functions of language is to facilitate the 'transmission' of thought from one language user to another. A number of scholars, including Sperber and Wilson (1995), and Tomasello (1999, 2003), have observed that verbal communication requires both a code – which is to say a language-system involving conventional symbols, pairings of form and meaning – and intentional mechanisms such as inference-reading abilities. While both these aspects are essential for verbal communication, communication can, in principle, occur in the absence of a code. Indeed, as we shall see, intentionality and the ability to recognize communicative intentions are likely to have been necessary prerequisites for the evolution of symbolic representation in language.

To function as a means of communication, an important prerequisite of a code, which is to say a language-system, is to be able to encode and externalize humanly-relevant concepts and combinations of concepts. Semantic knowledge, therefore, concerns the range and nature of humanly relevant concepts that can be expressed in language, and the way language serves to combine concepts in order to convey complex ideas. In this article, we explore (i) possible cognitive preadaptations for the development of semantic knowledge, and (ii) the range and nature of conceptual structure as encoded in language, and suggestions as to the way that this structure may have evolved.

Unlike some other aspects of language, there is scant evidence we can draw on in attempting to reconstruct the evolution of semantic knowledge. After all, we are, in essence, attempting to reconstruct the evolution of human cognition. To do this, we are

relying on indirect evidence drawn from primatology and comparative psychology, paleontology, evolutionary anthropology, and evolutionary psychology. Nevertheless, in view of some recent developments in linguistics, both in terms of uncovering and better understanding semantic phenomena, and recent theory-construction, we can now construct some plausible paths of semantic evolution that will at least facilitate further inquiry.

Cognitive Preadaptations for Semantic Knowledge

Language is characterized by being representational or 'symbolic.' That is, a language consists of a structured set of 'symbolic units' consisting of form and meaning components. While this definition represents the received view for lexical items, a growing body of scholarship argues that grammatical patterns can also be thought of as being inherently symbolic in nature (Langacker, 1987). Symbolic units consist of two further units: a phonological unit and a semantic or conceptual unit. The semantic unit, which is what we are concerned with here, has been variously termed a 'lemma' (Levelt, 1989) or a 'lexical concept' (Evans, 2004). In this section, we approach the evolution of semantic knowledge in a general way by considering the cognitive preadaptations that may have paved the way for the emergence of semantic knowledge.

The Importance of Motor Evolution

Donald (1991, 1999) has argued that there were two essential prerequisites for the evolution of symbolic units. One defining characteristic of language is that it can represent a particular idea or entity in the absence of a concrete cue: the design feature of language known as 'displacement.' For this representation to occur, hominids had to gain conscious access to their own memories (Donald, 1999). A second and crucial preadaptation for the emergence of language was the development of voluntary motor control. That is, hominids must have developed the ability to attend to their own action patterns, and to select, trigger, and 'edit' action pattern sequences. According to Donald, this development gave rise to 'mimesis,' a form of nonlinguistic representation. Mimetic action is representational in that it relies on perceptual resemblance to represent itself. For instance, hominid tool use, which can be traced back 1.5 million years, may have employed mimetic representation not only for showing and learning how to employ a tool, but through 'editing' motor routines through rehearsal, to improve the way in which the tool was used. Forms of representation such as mime, dance, ritual acts, and some kinds of music are also mimetic, serving as a form of communication that is nonlinguistic in nature. According to Donald, mimetic action was the earliest form of communication, upon which the later development of language may have been built.

While voluntary control of the musculature must have been important in the rise of this early and basic form of communication, and presumably also facilitated the later development of phonetic abilities and phonological systems, for Donald, linguistic representation is of a different kind from mimetic representation. While mimetic representation is holistic, a key characteristic of semantic knowledge, as represented by the inventory of lexical concepts available in the languages of the world, is that symbolic units serve to 'parse' sensory or perceptual experience into component parts, e.g., tree versus rock versus mountain, and even to encode a particular perspective with respect to which a component is viewed. For, instance, 'shore' and 'coast' both encode the same strip of land at the edge of the sea, but do so from different perspectives. Thus, for Donald, the importance of mimetic representation was that it created an appropriate cultural context, what he terms 'mimetic culture,' in which communication took place, and more precise disambiguation could occur with the advent of linguistic representation.

The Importance of Intention-Reading Skills

Another important preadaptation for the development of semantic knowledge is likely to have been the emergence of the ability to read intentions. According to Tomasello (1999), this sort of ability was the crucial preadaptation required for the evolution of symbolic abilities such as language more generally. Research in developmental psychology reveals that during early ontogeny, shortly before a year old, human infants begin to experience themselves as 'intentional agents.' That is, they perceive themselves as beings whose attentional and behavioral strategies are goal-directed. Accordingly, human infants also come to see others with whom they identify, conspecifics, as intentional agents. Crucially, it is shortly after this ontogenetic 'breakthrough' that language begins to emerge (Tomasello, 2003). Later, from around the age of three, human infants begin to develop the notion of themselves and conspecifics as 'mental agents.' This development constitutes the emergence of the 'theory-of-mind,' in which children develop the ability to conceive that others can hold different views from their own.

The importance of viewing oneself and conspecifics as intentional agents is far-reaching. From this view, it follows that others are intentional agents who possess

mental states that can be directly influenced and manipulated. For instance, pointing at an object can cause one intentional agent – who recognizes the person doing the pointing as an intentional agent attempting to direct attention – to follow the direction of pointing and thus share a 'joint attentional frame' (Tomasello, 1999, 2003). Thus, from this perspective, the importance of a lexical concept being associated with a particular linguistic form is in the utility of the symbolic unit in affecting the mental state of another in some way, such as by coordinating behavior. In other words, language, and the lexical concepts encoded by language, require intention-reading skills, which derive from the awareness that conspecifics represent intentional agents whose mental states can be influenced and manipulated by language.

A number of scholars view intention-reading abilities as an outcome of earlier evolutionary developments. For instance, Whiten (1999) argued that intention-reading skills constitute the outcome of the emergence of what he termed 'deep social mind.' This result can be characterized by cooperative behaviors including the sharing of food, monogamous reproduction – which has been claimed to be the ancestral pattern for humans – and behavior such as communal hunting. Indeed, Whiten argued that intention-reading abilities would have been essential for coordinating activities such as hunting, success at which requires being able to read the intentions of cohunters, and possibly also the prey.

Intention-reading skills most likely evolved by reading observables, such as direction of gaze, direction of motion, and so on. Thus, intention-reading skills are likely to have emerged from behavior-reading skills. On some accounts, chimpanzees are capable of rudimentary intention-reading abilities. Thus, intention-reading might be more than 6 million years old (Byrne, 1999), the time when hominids and chimpanzees separated.

Some scholars have argued that intention-reading in hominids can be viewed as a consequence of a long chain of evolutionary development. For instance, Savage-Rumbaugh (1994) suggested that bipedalism may have set in chain a series of evolutionary developments that gave rise to the cognitive ability to take the perspective of others (intention-reading). For instance, while chimpanzees and gorillas are distinguished from orangutans by a kind of quadrupedal locomotion termed 'knuckle-walking,' early hominids, the australopithecines, who emerged sometime between 4 and 5 million years ago, were distinguished by bipedalism. According to Savage-Rumbaugh, knuckle-walking and bipedalism were distinct and independent solutions to traversing open terrain and transporting infants. However, a consequence of bipedalism, but not knuckle-walking, is that the parent would have had to pay more attention to the infant, which is carried in the arms. In particular, the parent must remember to pick the child up after it has been put down. This consequence may have led to the later evolution of being able to take the perspective of others.

Table 1 Human intention reading abilities

Human intention reading abilities include . . .
The ability to coordinate or share attention, as when an infant and adult both attend to the same object
The ability to follow attention and gesturing, as when an infant follows an adult's pointing or gaze, in order to attend to an object
The ability to actively direct attention of others, such as drawing attention to a particular object or event, for instance, through pointing
The ability of culturally (imitatively) learning the intentional actions of others, such as imitating verbal cues in order to perform intentional actions such as declarative, interrogative or imperative speech functions

Similarly, Byrne (1999) argued that there may be more remote evolutionary antecedents for intention-reading abilities. One hypothesis is that our relatively large brachiating ancestors, for whom a fall would have been deadly, may have accomplished arboreal locomotion by advance planning. The mental representation of self as an entity moving through space would have prefigured representational abilities in general, and would have facilitated planning a trajectory of motion. Self-representation, and the ability to consciously plan one's movements are cognitive achievements that imply intentionality, and the later evolution of intention-reading skills. The suite of intention-reading skills evident in modern humans is summarized in Table 1.

The Importance of Personality Types

This issue concerns the idea that the earliest lexical concepts may have related to personality traits (King *et al.*, 1999). Recent research suggests that personality traits are stable across time and between contexts, correlate with verbal and nonverbal behaviors, and can be reliably judged by human observers. Moreover, King *et al.* (1999) argued that such behaviorally-signaled personality traits as reliability, dominance, and trustworthiness are directly relevant to complex social interactions involving competition, cooperation, sharing, sexual selection, and so on. King *et al.* (1999) suggested that it is the context-independent nature of such complex personality traits, and their importance for hominids that suggests such traits may have been encoded as the earliest lexical concepts.

For instance, studies that have sought to teach chimpanzees to manipulate symbolic units have found

that for symbol use to succeed, meaning must be decontextualized. Consider the example of an apple. If a symbol is applied to this referent, it is not clear which properties of the scene the symbolic form relates to. For instance, it could refer to the apple's color, shape, or that it is an item of food. Until the referent has been experienced in a number of contexts, it is not clear which aspect of the referent is being indexed, and thus what the lexical concept is that is being associated with the form. As personality traits are context-independent and readily identifiable by observers, then an early linguistic form that indexed a particular personality trait might have served as an early lexical concept. That is, personality traits achieve the displacement aspect of lexical concepts by virtue of being inherently context-independent. For this reason, symbolic representation in language may have taken personality traits as the first lexical concepts.

The Nature and Evolution of Semantic Knowledge

In this section, we examine the nature of semantic knowledge in more detail. That is, we examine how humans organize the world and their experience of the world into concepts. We also speculate on possible evolutionary bases of semantic knowledge of this kind and the cognitive mechanisms underlying this knowledge.

Concept Formation

'Semantic structure' constitutes the meaning system directly expressed by and encoded in language. In other words, semantic structure is the form that conceptual structure takes for expression in language. Thus, in order to get a sense of the nature of semantic knowledge, for instance, the nature and range of lexical concepts, we must begin by examining the nature of conceptual structure. In this section, then, we consider the basic units of concept structure, 'concepts.' We consider the following question: Where do concepts come from?

For psychologists, concepts are the basic units of knowledge and are essential both for 'categorization' – the ability to identify individuals, entities, and instances – and 'conceptualization' – the ability to construct alternative perspectives (Barsalou, 1992). To illustrate the notion of conceptualization, consider the sentences in (1) and (2). Each provides a different conceptualization of the concept Book:

(1) That book is heavy.

(2) That book is boring.

While the example in (1) relates to the book 'as tome,' the example in (2) relates to book 'as text.'

Since the work of the French philosopher René Descartes in the 17th century, who developed the principle of Mind/Body dualism, there has been a common assumption within philosophy and, more recently, the other cognitive sciences, that conceptual structure can be studied without recourse to the body, and hence without recourse to 'embodiment.' In modern linguistics, this 'objectivist approach' has been most evident in the approach to meaning known as 'Formal Semantics.' Proponents of this approach assume that it is possible to study meaning as a formal or computational system without taking into account the nature of human bodies or human experience. This position is problematic from an evolutionary perspective as it entails that a new discontinuous cognitive adaptation was required for conceptual structure. Conceptual structure, on this account, is assumed to employ what has been termed an 'amodal' (nonperceptual) form of representation. Amodal representation is distinct from the 'modal' or perceptual forms of representation that presumably had to exist prior to the emergence of conceptual structure, in order to represent 'percepts' (Barsalou, 1999).

The last two decades or so have seen a shift from modeling conceptual representation in terms of amodal systems, towards a more perceptual-based or 'embodied perspective.' An embodied perspective takes the view that concepts derive from percepts, and thus, conceptual structure is fundamentally perceptual in nature. Within linguistics, this general perspective has been advocated most notably by Lakoff and Johnson (1980, 1999; Lakoff, 1987), and also by Jackendoff (1983, 1992, 2002).

In general terms, the idea is that concepts have an embodied character. This idea constitutes the thesis of embodied cognition (see Ziemke, 2003 for discussion).

The idea that concepts are embodied assumes that we have a species-specific view of the world, due to the nature of our physical bodies.

One obvious way in which our embodiment affects the nature of experience is in the realm of color. While the human visual system has three kinds of photoreceptors or color channels, other organisms often have a different number. For instance, the visual system of squirrels, rabbits, and possibly cats, makes use of two color channels, while other organisms, for instance, goldfish and pigeons, have four color channels (Varela *et al.*, 1991). Having a different range of color channels radically alters how the world of color is perceived. This difference affects our experience of color in terms of the range of colors accessible to us along the color spectrum. Moreover, while some

organisms can see in the infrared range, humans are unable to see in this range (Jackendoff, 1992). It's clear, then, that the nature of our visual apparatus – an aspect of our physical embodiment – determines the nature and range of our visual experience. The position that different organisms have different kinds of experiences due to the nature of their embodiment is known as 'variable embodiment.'

The position that our experience is embodied – that is, structured in part by the nature of the kinds of bodies/neuro-anatomical structure we have – has consequences for conceptual structure. This corollary follows because the concepts we have access to, and the nature of the 'reality' we think and talk about, is a function of our embodiment. In other words, we can only talk about what we can perceive and think about, and the things that we can perceive and think about derive from embodied experience. Hence, the human mind must bear the imprint of embodied experience.

Some psychologists have made specific proposals as to how embodied experience gives rise to concepts. For instance, the developmental psychologist Jean Mandler (2004) suggested that through a process of 'perceptual meaning analysis,' percepts come to be recoded as concepts. Mandler argued that this process occurs alongside percept formation and begins virtually from birth. However, she viewed percepts and concepts as wholly distinct forms of representation. Another view has been proposed by Barsalou (1999). He argued that a concept is akin to a remembered perceptual state, which he termed a 'perceptual symbol.'

From an evolutionary perspective, if it is correct that concepts are fundamentally perceptual in nature, then by virtue of early hominids gaining conscious access to the contents of their own memories, little additional complexity in terms of cognitive development is required for a rudimentary conceptual system to have emerged. This corollary follows as concepts, on this account, are something akin to 'remembered percepts.'

The Nature of Lexical Concepts: The Natural Partitions Hypothesis

Having examined conceptual structure, we now turn to semantic structure.

Linguists have traditionally classified lexical concepts into those that are encoded by 'open' versus 'closed class forms.' Open class forms include, for English, nouns, verbs and adjectives, while closed class forms include determiners, prepositions, conjunctions, and so on. The basic insight is that it is much harder to add new members to the closed class set than to the open class set. A related insight is that open class forms tend to have much richer denotational meaning, while closed class forms are associated with lexical concepts that have more schematic or relational meaning. That is, they provide connections to other lexical concepts that have a more referential meaning.

However, since at least the early 1980s, the strict separation between closed and open class concepts has been called into question. This query stems from the observation that the division between open and closed class concepts constitutes more of a continuum rather than a strict bifurcation. For instance, Gentner (1981) pointed out that verbs, which are normally thought of as being open class, are highly relational in nature, a feature associated with closed class elements.

More recently, Gentner and Boroditsky (2001) have elaborated on this view, suggesting that open class lexical concepts exhibit 'cognitive dominance.' This contrasts with closed class concepts that exhibit 'linguistic dominance.' These notions relate to the similar idea expressed by Langacker (1987), who used the terms 'conceptually autonomous' versus 'conceptually dependent.' The basic idea is that lexical concepts associated with prototypical open class (autonomous) forms obtain their reference independently of language, which is to say from the world, while prototypical lexical concepts associated with closed class or relational forms obtain their reference from language. Moreover, whether a form is cognitively dominant (or autonomous) or linguistically dominant (or dependent) is a matter of degree. A proposed continuum is given in Figure 1.

In order to account for the cognitive dominance of prototypical open class lexical concepts (i.e., nouns), Gentner (1981) proposed the Natural Partitions Hypothesis. This idea holds that concepts that are encoded as prototypical open class elements such as

Figure 1 Division of dominance among form classes of lexical concepts. (Adapted from Gentner and Boroditsky, 2001: 216.)

individuals and objects are 'individuated.' That is, entities of this kind constitute densely bundled collections of percepts. Thus, an entity such as a rock or a tree 'stands out.' In Gestalt Psychology terms, a rock constitutes the figure in the figure-ground organization of a given scene. The Natural Partitions Hypothesis states that certain aspects of the world are given by the world. These entities are typically encoded crosslinguistically by nouns, and are acquired first by children. On this account then, bundles of percepts are 'given' by the world, and are simply labeled by language.

The Natural Partitions Hypothesis offers an intriguing insight into a possible order of evolution among lexical concepts – which is to say concepts encoded by language. That is, we might speculate, based on this, that the very first lexical concepts were those for individuals, including animals (and possibly classes of animals) and objects. Concepts of this kind have the most cognitive dominance. That is, they have highest conceptual autonomy. Other lexical concepts may have evolved later.

Further, there is a correlation between the position of a lexical concept on the continuum of dominance (see Figure 1) and the form class associated with the lexical concept. Although this correlation is not exact, for instance, 'destruction' and 'destroy' encode a similar concept employing different lexical classes (noun versus verb), it is plausible that the evolution of lexical classes (or 'parts of speech') emerged due to distinctions in the relative dominance or autonomy being further, later, encoded by morphosyntactic properties of language.

Lexical Concepts and Concept-Combination

From an evolutionary perspective, being able to form concepts and express them via language, while a remarkable achievement, doesn't begin to approach the range and complexity of the semantic structure available to modern Homo Sapiens. Lexical concepts are only a subset of our semantic knowledge. Another important aspect of semantic knowledge concerns our ability to combine lexical concepts in order to give rise to new and different kinds of conceptual structure. Moreover, it is a striking fact that concept combination produces complex concepts that are not simply the sum of the individual parts that comprise the derived concept. For instance, the complex concept Petfish is not simply the intersection of the concepts Pet and Fish. Rather, the concept Petfish has its own concept-internal structure, known as 'category structure.'

For instance, while most people would rank mackerel, which is silver in color, as a good example of the Fish category, a cat or a dog would be rated as a good example of the Pet category. Yet, a good example of a Petfish is a goldfish. Not only is a goldfish not silver, it is not soft and cuddly either. An important task in developing an evolutionary perspective on semantic knowledge is to account not only for the way in which lexical concepts are formed, but also for the mechanisms responsible for concept combination.

A recent approach to concept combination of this kind argued that complex concepts result from a process of 'conceptual integration' (Fauconnier and Turner, 2002; Turner and Fauconnier, 1995). This process involves what is termed 'selective projection' of content from each of the concepts that give rise to the complex concept, as well as additional material derived from background knowledge, such as knowledge that the kinds of fish we keep in fishbowls are typically goldfish. This process is termed 'completion.' Thus, the complex concept, known as a 'conceptual blend,' has structure associated with it that is found in neither of the 'input' concepts that give rise to it. This structure is diagrammed in Figure 2.

Clearly, some form of conceptual integration allows humans to combine and manipulate concepts in order to produce more complex ideas. Fauconnier and Turner argued that the emergence of cognitively modern human beings, during the upper paleolithic era, somewhere in the region of 50 000 years ago, points to the development of a new cognitive ability: our ability to perform conceptual integration. While anatomically modern humans appear to have existed from at least 100 000 years ago, the upper paleolithic stands out. This period witnessed the emergence of new social and technological breakthroughs, including the development of projectile points made from bony material for use in hunting, the manufacture of personal adornments, the development of sophisticated art, evidence of belief systems such as religion and magic, plus manmade shelters were built for the first time, sewn clothing was worn, and sculptures were produced. Fauconnier and Turner argued that what made advances such as these possible, was that humans had evolved the ability to perform complex conceptual integrations. This process, then, may have facilitated composing and elaborating concepts to produce new and more elaborate conceptual structures.

Polysemy

Another striking aspect of semantic knowledge is the phenomenon of 'polysemy.' This aspect constitutes the way in which a range of related lexical concepts can be expressed using a single form. For instance, the English preposition 'over' has a number of distinct but related lexical concepts associated with it.

Figure 2 Conceptual integration for the composite concept *goldfish*.

Consider some of the distinct lexical concepts proposed by Tyler and Evans (2003):

(3a) The picture is over the sofa ['above']
(3b) The picture is over the hole ['covering']
(3c) The ball is over the wall ['on-the-other-side-of']
(3d) She has a strange power over him ['control']
(3e) The government handed over power ['transfer']
(3f) She prefers wine over beer ['preference']
(3g) The relationship is over ['completion']
(3h) The relationship evolved over the years ['temporal']
(3i) The fence fell over ['reflexive']
(3j) They started the race over ['repetition']

Recent research has argued that polysemy, far from being merely a 'surface' phenomenon, is in fact conceptually real. That is, polysemy patterns reflect distinct lexical concepts, stored as different senses in the mental lexicon (Evans, 2004; Lakoff, 1987; Tyler and Evans, 2003). Accordingly, from an evolutionary perspective, the challenge is to explain how the proliferation of lexical concepts, i.e., polysemy, arises.

A recent perspective is that polysemy emerges from the interaction between language use and contexts of use, due to the conventionalization of situated (or invited) inferences (Traugott and Dasher, 2002; Tyler and Evans, 2003; Evans, 2004). For instance, the 'covering' meaning associated with 'over' may have derived from contexts of use in which, in a given spatial scene, an element placed above another entity thereby covered it. Through a process of decontextualization, the 'covering' meaning was reanalyzed as being a distinct meaning component. Once this reanalysis occurred, it could be used in novel ways unsupported by the original spatial scene that gave rise to the inference in the first place (Tyler and Evans, 2003).

From an evolutionary perspective, the importance of polysemy and meaning-extension is that it illustrates how language, in conjunction with human experience, can give rise to new lexical concepts. Moreover, this particular phenomenon of meaning-extension illustrates how language can flexibly increase its repertoire of lexical concepts without increasing the number of linguistic forms.

Abstract Concepts

Another important aspect of semantic structure relates to so-called abstract concepts. These include lexical concepts such as Truth, Justice, or Theory. Concepts of these kinds are abstract in the sense that they cannot be straightforwardly accounted for in terms of perceptual recording, precisely because it's not clear what their perceptual basis is, and even whether they have one. Indeed, abstract concepts provide a significant challenge if we are to attempt to provide an evolutionary account maintaining the thesis of embodied cognition.

An influential framework that provides an account that is based in perceptual or embodied experience is the 'conceptual metaphor theory' of Lakoff and Johnson (1980, 1999). Lakoff and Johnson argued that abstract concepts are grounded in embodied experience, and thus our perception of the world, even if the grounding is not direct. This grounding is achieved by virtue of 'conceptual metaphors,' which are long-term conceptual mappings that serve to project structure from a 'source concept,' which relates to perceptual experience onto the abstract concept, the 'target concept.' For instance, we commonly understand the abstract concept of Quantity in terms of the more perceptually concrete concept of Verticality, as evidenced by examples such as the following:

(4a) The price of stocks has **gone up**.
(4b) Her score is **higher** than mine.

In both these examples, an abstract notion of Quantity is understood in terms of physical position or motion on the vertical axis. This understanding is licensed by the conceptual metaphor Quantity Is Vertical Elevation.

The most recent version of conceptual metaphor theory recognizes two distinct kinds of conceptual metaphors: 'primary metaphors,' which are directly grounded in experience and constitute 'primitive' conceptual mappings, and more complex 'compound metaphors,' which are constructed out of the more experientially basic primary metaphors (Grady, 1997; Lakoff and Johnson, 1999).

For instance, when we understand Theories in terms of Physical Structures, as evidenced by the following examples:

(5a) Is that the **foundation** for your theory?
(5b) The argument is **shaky**.

Grady argues that the motivation for linguistic examples such as these is in fact two primary metaphors, Persisting Is Remaining Erect and Organization Is Physical Structure. These unify to give the compound metaphor An Abstract Organized Entity [such as a theory] Is An Erect Physical Object (Grady, 1997).

Thus, it is only primary metaphors that are grounded in perceptual experience. The motivation for the conceptual associations captured by primary metaphors is due to a tight and ubiquitous correlation in experience. For instance, there is a tight and recurring correlation in experience between quantity and height. When we fill a glass with water, an increase in quantity correlates with an increase in height. Thus, primary metaphors are motivated by 'experiential correlation.'

From an evolutionary perspective, the phenomenon of 'metaphoric' mappings holding between concepts from different parts of 'conceptual space,' known as 'domains,' allows us to account for how perceptual information can be recruited in order to construct more abstract concepts, such as Quantity and Theories. This phenomenon suggests that, in addition to being able to recode percepts as concepts and combine concepts, the conceptual system must have additionally developed a mechanism for projecting structure from one conceptual domain to another in order to create more abstract concepts.

Cultural Evolution

The final issue we examine is that of cultural evolution. Lexical concepts are culturally embedded, and thus, we must briefly look at the role of cultural evolution in providing the conceptual backdrop for the emergence of semantic knowledge.

Consider the evolution of the concept of Money. This concept is one that has been evolving for over 3000 years. Weatherford (1998) identified a number of key mutations in the development of how we conceptualize Money. The first was the invention of coins in Anatolia over 3000 years ago. This development gave rise to the monetary economies that underpinned the classical Greek and Roman civilizations. The second was the development of family-owned credit banks in Renaissance Italy. This development gave rise to capitalist market economies that replaced earlier feudal societies throughout Europe, and the period in which European countries expanded to became global economic powers. The process whereby cultural artifacts or cultural practice undergoes cumulative evolution, resulting in modification or improvement has been dubbed the 'ratchet effect' (Tomasello, 1999). Thus, an important aspect of the evolution of semantic knowledge involves the development and evolution of cultural knowledge.

After more than a century of more or less avoiding the subject, linguists have become much more interested in questions about evolution in recent years. Arguably, this interest was kick-started by an important paper by Steven Pinker and Paul Bloom (Pinker and Bloom, 1990). The number of articles in this encyclopedia that are concerned with matters of evolution can be seen as evidence of this increased interest (see cross-references below). Jackendoff (2002: 231–232) suggests two reasons for the increased interest. One is that we now understand much more about evolutionary principles in general and about human origins in particular than we did a century ago. The other is that increased interest in evolution in general inevitably leads to increased interest in the evolution of language in particular and, as Bickerton suggests (Calvin and Bickerton, 2000), it is important for linguists to be involved in this discussion. At the same time, there is some ambivalence about this topic. Linguists are wary of debates on topics where the data is so limited and the discussion therefore has to be quite speculative. Despite this, there have been a number of interesting discussions in recent years and significant progress has been made in this area. There has also been a significant increase in work that considers how syntax in particular might have evolved. This essay begins by considering some general questions about the nature and evolution of language before considering questions about the evolution of syntax, and some of the answers that have been proposed. The two sets of questions are closely linked in ways that echo the connections between studies of language in general and studies of syntax in general.

Language

Before working out how a particular trait evolved, we first need to know what that trait is. There has been considerable disagreement about what 'language' is in the past and there are currently several different views (*see* the articles in this encyclopedia on **Linguistics: Approaches** and **Approaches to Translation, Linguistic**). Language can be viewed as a social or a cultural phenomenon as well as a psychological one.

After more than a century of more or less avoiding the subject, linguists have become much more interested in questions about evolution in recent years. Arguably, this interest was kick-started by an important paper by Steven Pinker and Paul Bloom (Pinker and Bloom, 1990). The number of articles in this encyclopedia that are concerned with matters of evolution can be seen as evidence of this increased interest (see cross-references below). Jackendoff (2002: 231–232) suggests two reasons for the increased interest. One is that we now understand much more about evolutionary principles in general and about human origins in particular than we did a century ago. The other is that increased interest in evolution in general inevitably leads to increased interest in the evolution of language in particular and, as Bickerton suggests (Calvin and Bickerton, 2000), it is important for linguists to be involved in this discussion. At the same time, there is some ambivalence about this topic. Linguists are wary of debates on topics where the data is so limited and the discussion therefore has to be quite speculative. Despite this, there have been a number of interesting discussions in recent years and significant progress has been made in this area. There has also been a significant increase in work that considers how syntax in particular might have evolved. This essay begins by considering some general questions about the nature and evolution of language before considering questions about the evolution of syntax, and some of the answers that have been proposed. The two sets of questions are closely linked in ways that echo the connections between studies of language in general and studies of syntax in general.

Language

Before working out how a particular trait evolved, we first need to know what that trait is. There has been considerable disagreement about what 'language' is in the past and there are currently several different views (*see* the articles in this encyclopedia on **Linguistics: Approaches** and **Approaches to Translation, Linguistic**). Language can be viewed as a social or a cultural phenomenon as well as a psychological one.

But any social or cultural phenomenon must be represented mentally, and psychological systems and processes must be involved at some stage in the spread of any phenomenon through a culture.

Even when seen as a psychological phenomenon, there is disagreement about what kind of thing language is, and different assumptions about this will have implications for theories of language evolution. To take one example, Hauser *et al.* (2002) claim that recursion is the one key feature of language seen as a mental faculty, while Pinker and Jackendoff (2005) see recursion as just one of several important properties of language. At a more general level, there is the question of how components of the language system such as phonology (the system of sounds), syntax (structure), and semantics (representations of meaning) are related. Could phonology exist independently of syntax? Could syntax exist independently of phonology? Could the use of symbols exist without the existence of structural representations? Even more generally, there is the question of how language relates to other parts of the mind. Fodor's 'language of thought' hypothesis (Fodor, 1975) suggests that our system of mental representations is both representational (has a kind of semantics) and computational (has a kind of syntax). If this is so, then we need to explore how the language of thought relates to our knowledge of natural languages, including the relationship between the syntax of the language of thought (which most theorists would assume to be universal) and the syntax of particular languages.

Evolution of Language

One of the most frequently discussed questions about the evolution of language concerns the speed at which it occurred. Was it a slow, incremental process where each stage developed independently after the previous one? Or did language emerge suddenly as something dramatically different from what had gone before? Another question concerns the nature of the evolutionary process. Pinker and Bloom (1990) suggest that language is a complex biological adaptation that evolved by natural selection, while other researchers have considered evolution as a cultural phenomenon rather than a biological one. Pinker and Bloom's work is partly motivated as a response to Chomsky's (1975) skepticism about an evolutionary account of language based on natural selection. While many researchers agree that a number of preadaptations made the development of language possible, there is disagreement on whether language emerged as an adaptation (so that language is now being used for the purpose for which it evolved) or, following Gould's (1991) terminology, an exaptation (where a trait that evolved for one purpose is then co-opted for another purpose). An exaptation can be either an adaptation that has been co-opted for a purpose different from that for which it originally evolved (such as feathers, which originally evolved because they helped keep birds warm but later turned out to be useful for flight) or side effects of adaptations, which then turn out to be useful in a different way. The latter are referred to as 'spandrels,' a term taken from architecture where it describes the spaces created as a side effect of putting two arches next to each other. Gould suggests that language could be a spandrel in the sense that it is a by-product of increased brain size that was beneficial for independent reasons. This view seems to be supported by Chomsky in one of his most well-known comments on evolution:

> We know very little about what happens when 10^{10} neurons are crammed into something the size of a basketball, with further conditions imposed by the specific manner in which this system developed over time. It would be a serious error to suppose that all properties, or the interesting properties of the structures that evolved, can be 'explained' in terms of natural selection. (Chomsky, 1975: 59)

Another general question concerns the relationship between the different features that together constitute human language. One important problem in developing an account of the evolution of language has to do with the perceived complexity of language and the large number of separate phenomena that together are involved in linguistic behavior: at least phonology, syntax, and semantics for the system itself, and at least intentionality and metarepresentational ability for the ability to communicate with it. While it is easy to see that full human language is likely to deliver an evolutionary advantage and so be favored by natural selection when it happens to emerge, it is not so obvious that any of these phenomena alone would deliver an evolutionary advantage. So it seems unlikely that a situation could arise where what we know as language could emerge and then be selected. This may be one reason for Chomsky's reluctance to entertain the possibility of an account of language evolution based on natural selection.

Partly despite and partly in response to this problem, discussion has focused on particular components of language and there has been ongoing discussion of the likelihood of various orders of emergence. Lieberman (1984, 1991, 1998), for example, has suggested that the ability to speak preceded the development of full language. He suggests that we first evolved all of the physiological resources to make speech possible and that this then made possible the development of full language. Corballis (2002), in

contrast, suggests that fully syntactic messages were conveyed by hand gestures along the lines of modern signed languages long before speech developed. Bickerton (2003) rejects Corballis's view, following Burling (2000) and Sperber and Origgi (2000) in assuming that prehumans had to be attempting some form of intention-recognition before any of the components of language could exist. While he suggests that symbolism might have preceded structure by "as much as two million years" (Bickerton, 2003: 81), he also suggests that syntax is central to language and that this was the crucial development which made language possible. Okanoya (2002) suggests that syntax might have developed before words so that semantic relationships emerged after syntactic structure. This is based on evidence from the study of finch song, where it seems that a rudimentary syntax evolved independently of meaning. Okanoya further suggests that there are links between syntactic abilities and sexual selection.

An account of the evolution of syntax will be located within this debate and will have to address the question of how syntax and its evolution relate to other components of language and their evolution.

One major issue for all work on evolution is the nature of the evidence. In work on the evolution of language, there is a wide range of approaches from a wide range of disciplines using a wide range of evidence types. Areas that provide, or could conceivably provide, evidence include animal communication, anthropology, archeology, artificial intelligence, cognitive neuroscience, comparative neuroanatomy, computer modeling, ethology, formal language theory, language acquisition, language disorders, mathematics and mathematical modeling, philosophy, psychological experiments, as well as more familiar linguistic and conceptual evidence. But of course since language itself leaves no fossils, all evidence is indirect.

Syntax

As suggested above, we cannot but assume that syntax is part of language seen as a psychological phenomenon (even if syntax-like combinatorial structure is also involved in thought and other aspects of the mind). So an account of the evolution of syntax must be part of an account of the evolution of language seen as a psychological phenomenon. As well as answering questions about the relationship between syntax and other components of language, any account of how syntax evolved will need to make assumptions about the nature of syntax itself and how it is related to other parts of the mind. Different answers to these questions lead to quite different accounts of the evolution of syntax. At one extreme, we might suggest that syntactic structure (in the sense of NPs and VPs) is necessary for combinatorial thought, and therefore that syntax is a necessary precursor to the development of full human language. At another extreme, we might suggest that syntactic structure emerges after the development of other phenomena such as the ability to speak and the ability to understand noises or gestures as representing particular meanings. To some extent, this is a question of the development and status of combinatoriality. Combinatoriality is a property of phonological and semantic knowledge, as well as of syntax. This raises the question of whether it arose in one of these areas first before developing in the other areas.

Chomsky has suggested that the properties of phonological structure and of semantic representations each depend on properties of syntax but not *vice versa*. In his view, syntax is fundamental to our linguistic knowledge. Jackendoff (2002) terms this 'syntactocentrism' and argues that it should be rejected. He proposes that language can be understood in terms of a 'parallel architecture' where phonology, syntax, and semantics are separate, equally generative, components that communicate with each other through 'interface' components. This question concerns us here because of the implications for an account of the evolution of syntax. Can we treat the evolution of syntax as separate from the evolution of phonology and semantics or do they depend on each other, mutually or in an ordered way (where the evolution of one preceded the evolution of the other)?

Recursion is a fundamental property of syntax, and an important part of an evolutionary account will concern how knowledge of recursive structures such as (1) evolved (*see* **Recursion**):

(1) Keith said that Billy thought that this was the book that annoyed the linguist who surprised the psychologist when he said that recursion was the most important defining property of human language.

What makes this recursive is the fact that it contains constituents that dominate other instances of the same syntactic category (for example, the sentence beginning *Keith said that…* dominates the sentence beginning *Billy thought that…*)

It is not only linguistic expressions that demonstrate recursion. Our thoughts too are recursive, in that we can embed thoughts within other thoughts, entertaining propositions such as that expressed by (2):

(2) Tom thinks that Mary said that Dan was wondering whether Frieda knew about the party.

It seems that we are the only creatures who have this ability to such an extent. Other primates can entertain thoughts about thoughts but only to a limited extent (see Tomasello and Hare, 2003), e.g., a chimp might be able to think that if he defends an empty container, another creature will think it is full; or recursive thoughts might be involved in a chimp working out a plan of action. This is, though, about as complex as such thoughts can get for chimps. Humans can entertain recursive thoughts quite easily and can also produce and understand linguistic expressions that are complicated in the same way. This leads to speculation that the evolution of syntax may have made possible both metarepresentation and also human language.

Evolution of Syntax

There has been a considerable amount of significant work on the evolution of syntax in recent years (a large amount of this work can be found in the collections edited by Christiansen and Kirby, 2003; Hurford *et al.*, 1998; Knight *et al.*, 2000; Wray, 2002). While no general consensus or dominant approach has yet emerged, we can identify a number of questions and themes that researchers have addressed. As mentioned above, many of these concerns overlap or mirror questions about the evolution of language as a whole. It is not possible here to do justice to the range of positions and themes that have been explored so far, but we run through a number to give a flavor of the kinds of issues currently being explored. At the end of this section, we give a more detailed sketch of Jackendoff's (2002) sketch of a possible series of stages in the evolution of (syntax and) language.

Is Syntax Adaptive?

As with other components of language, there are different views about whether syntax is adapative or not, and therefore whether it can be explained in terms of natural selection or not. Pinker (2003; Pinker and Bloom, 1990) and Bickerton (1981, 1990, 1998, 2002, 2003), among others, suggest that language and syntax are adaptive and so amenable to an account in terms of natural selection. Lightfoot (1991, 2000), in contrast, suggests that some properties of syntax are not adaptive and so they have evolved despite being dysfunctional. Part of the evidence is that individuals violate some of the constraints imposed by the syntactic system. Lightfoot argues that certain conditions are "dysfunctional, blocking expressions which are needed" (Lightfoot, 2000: 244). This means that they are spandrels and so could not have been selected for. He concludes that this is true of at least some syntactic conditions but does not rule out the possibility that the whole language system is a spandrel. Overall, a number of distinct positions have been taken with regard to the question of whether syntax, or language, is adaptive. The notion that syntax is adaptive is often linked to the observation that combinatoriality is a property not only of syntax but also of semantics, phonology, and thought.

Exaptation

Assuming a biological approach, one suggestion that has a significant number of supporters is that syntax is an exaptation from nonsyntactic structure. One possible line on this is that the mental representations involved in thought developed combinatorial structure and this was then taken over by the linguistic system. Alternatively, combinatoriality might have originated in phonology or in speech (Carstairs-McCarthy, 1999).

Biological or Nonbiological Evolution

Related to this is the question of whether explanations are proposed in terms of biology, of culture, or as developments within the language system itself. As we have seen, Bickerton and Pinker propose a biological account. Tomasello (2003) shares one part of Bickerton's view, namely that it is the separate evolution of symbols and grammar that distinguishes human communication from that of other primates. But he rejects Pinker's and Bickerton's view that it is specifically language that is adaptive. He suggests instead that language emerged as one part of the larger process of the evolution of human culture. In his view, the emergence of a broader kind of social cognition enabled human culture, and human symbolic communication should be seen as a special case of that. Worden (2000) proposes a model with a constant biological endowment which, together with specific learning mechanisms, enables the **cultural** evolution of languages. Hurford (2003) proposes a combination of biological preadaptations and learning-based linguistic adaptations. Jackendoff (2002) leaves open the question of how much is biological and how much cultural.

The 'Big Picture' and Details of Syntax

Hurford (2000: 222–224) raises the interesting issue of the relationship between programmatic, 'big-picture' statements and "the degree of detailed knowledge that has now been accumulated about the syntax of languages." He points out, for example,

the striking contrast between the simple syntaxes of the emergent languages in computer models and the complexity of real languages, which is familiar to linguists. He suggests that the value of programmatic proposals follows from the fragmented and rapidly changing nature of contemporary syntactic theorizing. The 'turmoil' of the field, he suggests, means that syntactic theorizing "needs to start looking beyond its traditional horizons for explanatory principles of kinds that it has not previously considered" (Hurford, 2000: 223).

A related contrast is between programmatic proposals and more specific suggestions. One of the boldest specific suggestions so far has been Newmeyer's (2000) suggestion, based on evidence from typology as well other work on language evolution, that the earliest forms of human language had rigid SOV word order.

Effects of Particular Developments Within Theories of Syntax

It is also interesting to consider how particular developments in syntactic theorizing relate to theories of the evolution of syntax. The Minimalist Program, for example, has been seen by some theorists (e.g., Berwick, 1998) as making evolutionary accounts more plausible, while others, including Chomsky himself (1991a, 1991b) have suggested that language is 'dysfunctional' with regard to processing and so makes an evolutionary account less likely. These conclusions rest, of course, on assumptions about how particular syntactic theories interact with other domains, such as theories of processing.

When Did Syntax Emerge?

Many researchers suggest that syntax emerged relatively late (around 40 000–150 000 years ago) and relatively quickly, but Burling (2002) suggests that it may have been a more gradual process starting much earlier. His evidence for this comes from looking at early and late stages of child language acquisition. He suggests that the acquisition of syntax spans a relatively long time in the development of an individual child and that this weakens arguments based on analogy with child language acquisition that the evolutionary development of syntax was abrupt.

How Many Stages?

Related to this is the question of the stages involved in evolution. Bickerton (1990, 1998, 2002, 2003; Calvin and Bickerton, 2000; see also Bickerton's article **Protolanguage** in this encyclopedia) has proposed that language evolved in two stages. The second step is the development of language as we know it now. The first step is the development of protolanguage. Protolanguage is a simpler system of communication than full human language where certain actions (sounds or gestures) represent certain meanings but without the full complexity that arises with the development of syntax. So protolanguage can be thought of as 'modern language without syntax.'

There are two particularly interesting things about this proposal. First, it suggests a way around the logical problem caused by thinking of human language as one entity and so suggests how we can develop an incremental account of language evolution. Protolanguage would bring advantages and therefore 'be worth selecting for its own sake.' Second, Bickerton suggests that protolanguage is still present in the human brain and can be seen in a number of situations where language is disrupted or not developed. Cases of disruption include the development of pidgin languages when distinct language groups are thrown together and need to find a way to communicate without a full shared language (Bickerton, 1981), cases such as that of 'Genie' (Curtiss, 1977), where an individual is denied the necessary environmental triggers until it is too late for her to acquire full language, and possibly cases of agrammatic aphasia, language disorders that affect syntactic processing. Cases where language has not developed include early child language and communication systems developed by apes when humans attempt to teach them language (Linden, 1974; Savage-Rumbaugh *et al.*, 1998). The suggestion is that protolanguage emerged, was useful and favored by natural selection and that this made possible the subsequent development of human language with complex syntax.

A Series of Stages

Bickerton (1990) initially saw the development from protolanguage to modern language as one great leap, but has since (Calvin and Bickerton, 2000) developed a more gradualist position. Jackendoff (2002) proposes a much more incremental story. He suggests that it is possible to reconstruct from modern human language a sequence of distinct innovations from primate calls, each of which is an improvement in communicative expressiveness and precision. He suggests, furthermore, not only that the earlier stages are present in the brain but also that their 'fossils' are present in the grammar itself, and so are available as evidence. A summary of the steps proposed is shown in Figure 1.

Figure 1 Summary of incremental evolutionary steps (from Jackendoff 2002: 238).

Working downward through Figure 1, the first step and the two steps on the left of the figure (use of symbols, open class of symbols, phonological combinatorial system) take us beyond primate call systems but do not come close to full modern language. The development of a phonological combinatorial system is an important step here. As the number of symbols becomes larger, it becomes harder to make them all memorable and discriminable. If the symbols were holistic, it would not be possible to keep even a thousand of them distinct in perception and memory. This problem is solved in modern language by building words up combinatorially from a few dozen smaller meaningless speech sounds, the phonemes.

The first step toward modern syntax is to concatenate more than one symbol into a single utterance, with the connection between them determined purely by context. Concatenating more than two symbols multiplies the number of possible meanings, though much depends on exactly which symbols are used. This is different from the combination of sounds just mentioned, in that meaningful symbols are combined to form larger utterances whose meanings are a function of the meanings of the symbols used. In 'protophonology,' in contrast, meaningless symbols are combined to form meaningful ones.

Concatenating symbols opens up many opportunities for enhancing expressive power and precision.

Two important classes of innovations are orthogonal: using the linear order of concatenated symbols to express relations between them, and introducing new sorts of vocabulary item that convey relations explicitly. On this view, the former is a stage on the way to Bickerton's protolanguage, while the latter (discussed below) is a stage later than protolanguage on the way to modern language.

With just symbol concatenation, interpreting particular utterances depends very much on contextual inference. Pinker and Bloom (1990) suggest that this means that using principles of word order would be communicatively adaptive. Some principles of word order will narrow down the range of possibilities and lead to a system roughly equivalent to Bickerton's protolanguage.

An important step in moving from protolanguage to modern language is to develop the means to represent relations not just between words but also between phrases. In a sentence such as *the careless boy lost his brother's apple,* it is the entire phrase *the careless boy* that enters into a semantic relation with the verb *lost*. This collection of words functions as an elaborated version of the single word *boy*, the head of the phrase. More generally, a noun phrase is an elaborated version of a noun, an adjective phrase is an elaboration of an adjective and so on.

When headed phrases appear, then principles of word order can be elaborated into principles of phrase order. This means that the messages that can be conveyed are much more complex: not just *dog chase mouse*, for example, but also *[big dog with floppy ears and long scraggly tail] chase [little frightened mouse]*. It also makes possible hierarchical embedding such as *[the dog [that bit the cat [that chased the rat]]]*. This hierarchical embedding is one of the hallmarks of modern language but it is neither simple nor inevitable, even in a generative representation. It does not occur so relentlessly in phonological structure, for example.

This potential complexity raises new problems of communicability. With only three words in a sentence, the relations among them can be conveyed by simple word order plus pragmatics. But when sentences are longer and grouped into phrases, it becomes much more important to make phrase boundaries and the semantic relations among words explicit to the hearer. Language needs further devices than linear order and intonation in order to make semantic relations explicit.

One way to encode semantic relations among words and phrases is to invent words that express them. Relational words are pointless at the one-word stage but are useful once we have multiple-symbol utterances. The next step is the development of grammatical categories, and Jackendoff makes some suggestions about how the distinction between nouns and verbs might have arisen.

Two more changes are needed to move from this point to modern language: the development of morphology and the remaining aspects of syntax. Bickerton and many other linguists treat these as an integrated whole at the core of grammar, but Jackendoff suggests that we might see phrasal syntax and morphosyntax as independently evolved systems, each built on top of the system of protolanguage, each refining communication through its own expressive techniques.

On this speculative picture, then, modern language evolved from primate calls in a number of stages, each step having its own advantages over the step before. This suggests not only that the evolution of language can be seen as happening in a number of discrete steps but also that the syntactic component itself can be further broken down and that syntax itself may have developed in a series of discrete steps. This leaves open the important question of which of these steps require biological evolution and which could be the consequence of cultural innovation.

Conclusion

Some linguists are reluctant to discuss a topic where the data is so remote. But the data of 'everyday' linguistics is also remote in that it is buried in the minds of language users at a level not accessible to consciousness. Recent work means that we now have a fuller understanding of evolution in general and linguists have been working on formulating and testing clearly stated hypotheses on the evolution of language, including the evolution of syntax. Continuing developments in the study of language and syntax have also helped linguists make significant progress in our attempt to understand the nature of syntax and language and how they evolved. While there is as yet no general consensus, there is a clear sense of an emerging interdisciplinary research program concerned with the evolution of language in general and with the evolution of syntax in particular.

Research into language evolution is alive and well, as evidenced by a healthy mixture of agreement and disagreement among its participants.

Is Language Evolution Research Worthwhile?

Before we discuss current issues within the field of language evolution, it is worth mentioning a basic disagreement between researchers in this field and other language researchers outside it. This most fundamental issue is whether anything at all sensible can be said about the evolution of language. A body of researchers from a wide variety of disciplines, including archaeology, anthropology, artificial intelligence, cognitive science, ethology, genetics, linguistics, mathematics, philosophy, and psychology, are clearly of the opinion that something sensible can be said, and a growing number of books, journal articles, and conferences attest to this commitment. However, it is noticeable that relatively few linguists participate in these activities, and many linguists either believe that nothing solid can be said on the subject or that questions of evolution are peripheral to the main study of language. These differences are rooted in the history and sociology of the various academic disciplines.

Much mainstream theorizing about the nature of language from within the field of linguistics is solidly within a structuralist mould and tends to take into account a quite narrow range of data, centered mostly on judgments about particular examples. The explanatory principles typically postulated by linguists are specific to language (i.e., not applicable to facts outside language) and are quite abstract. The general aim is like that of physics, to arrive at a parsimonious set of axioms from which the facts (in this case, facts of language) can be derived. Within mainstream linguistics, it is usually assumed that such axioms will be specific to language. To outsiders (e.g., anthropologists or biologists), such concentration on the structure of particular sets of linguistic examples, and the concomitant language-specific theory-building, is something of a mystery, or at least an esoteric avenue unlikely to be conclusive on its own. It is natural that anthropologists should believe that at least some properties of language are the result of its use in societies, that animal behavior researchers should look for parallels between animal communication and cognition and human language, and that computational and mathematical modelers of language evolution should appeal to principles of self-organization found in other complex dynamic systems.

What unites the nonlinguist researchers in language evolution is a belief that evolutionary processes in themselves can help to explain how language came to be as it is. They subscribe to Dobzhansky's (1973: 125) slogan, "Nothing in biology makes sense except in the light of evolution." Linguists, however, have largely been trained in a tradition that pays little or no attention to evolutionary processes, even while the core of the mainstream position on language is that language is a biological phenomenon. Dobzhansky's focus on 'making sense' in his famous quotation points to the central motivation of language evolution research; namely, to see language in such a light that it makes sense. Thus, the goal of language evolution research is much less the answering of (apparently) factual questions like, 'What was the first human language like?' 'To what extent was language developed in *Homo erectus*?' and 'When did recursive syntax first appear?' than establishing connections between the findings of all the disciplines concerned with human behavior in such a way that the facts of language, as described in detail by linguists, make sense. 'Making sense' is, of course, a quite vague phrase that needs to be nailed down more precisely. Here we are at the mercy of the extreme complexity of our subject matter. A human language is the outcome of the interplay of many factors – both biological and social – all subject to noise and random accident. Nevertheless, language evolution researchers share the belief that taking evolutionary processes, broadly conceived, into account helps us to achieve some understanding of why language is the way it is.

How Much About Language Is Special?

This question is often called the 'question of domain-specificity.' Humans are the only species with language. This could be because humans have greater general cognitive capacity than other species, and each element of our linguistic prowess has a counterpart in some nonlinguistic domain of human behavior. For instance, it has been argued by Christiansen and Ellefson (2002) that the preferences seen across languages for certain orderings of heads and modifiers arise from the fact that such orderings are easier to learn by a neural net, that is a general-purpose learning device, rather than a learning device specifically devoted to language. Another example of a suggestion that an ability deployed for use with language is not an adaptation specifically for language is implicit in the finding by Kuhl and Miller (1978) that chinchillas are sensitive to exactly the same auditory

distinction between voiced and voiceless sounds as humans; this aspect of human hearing, it can be concluded, is not specific to the human language capacity, because we share it with chinchillas, who do not have any language capacity. An extreme position on this question would claim that there is no aspect of human linguistic behavior special to language. In fact, such an extreme view would mean that there is no specifically linguistic faculty.

Linguistic theory from the 1950s to the 1990s was dominated by a view that humans are endowed with a specifically linguistic faculty that is richly structured. In other words, there is a lot of information in the language faculty that cannot be found in any domain outside language. It was the goal of linguistic theory to spell out the complex nature of this faculty, variously referred to as UG (universal grammar) and the LAD (language acquisition device). See Chomsky (1965, 1975, 1981) for successive articulations of this research program. This represents a position at the other end of the spectrum from the 'no specific language capacity' position. This 'rich language faculty' position is coupled with a strongly nativist position, claiming that the rich details of this faculty are encoded in the genes and transmitted via DNA.

More recent theorizing has reversed the direction of the previous four decades, and the 'Minimalist Program' (Chomsky, 1995) claims that the human language faculty is in fact not very richly structured at all. A stimulating paper by Hauser *et al.* (2002) suggests that the human language faculty may consist of nothing more than the capacity for recursive computation, with even a hint that if recursion can be found in the cognitive capacities of nonhuman animals, the specifically linguistic faculty of humans may be zero (i.e., it may not exist). The paper by Hauser *et al.* makes the useful distinction between FLN (faculty of language in the narrow sense) and FLB (faculty of language in the broad sense). FLB includes capacities that support language but that also (arguably) support other nonlinguistic abilities – capacities such as normal hearing, control of breathing, short-term memory, and logical inference. The discussion above concerns FLN. A more conservative view, reflecting preminimalist theorizing, and claiming that the language faculty is indeed special in many more ways than just involving recursion, is expressed by Pinker and Jackendoff (2005). Jackendoff (2002) has related such arguments to evolutionary issues, postulating eight discrete stages toward the evolution of modern language.

How Much of Language Is Adaptive?

The question of how much of language is special (or how much is in FLN) has direct implications for language evolution. If the innate language faculty is rich in detail, these details must have arisen through biological evolution, and most researchers envisage that natural selection must have played a major role in this evolution. Natural selection, the argument goes, produces structures that are adapted to those functions that help an organism survive and reproduce. Before the rise of the Minimalist Program, while linguistic theorists (at least within the generative tradition) mostly still subscribed to the view that the language faculty is rich in information, there was disagreement about how much of this rich detail had been selected by natural selection. Theorists who all agreed that the language faculty is a rich complex of separate specifically linguistic principles disagreed on how it had come to be that way. A highly influential paper by Pinker and Bloom (1990) argued strongly that the most obvious and least controversial explanation for the innate principles of language was natural selection. They compared the evolution of the language faculty with the evolution of the mammalian eye; both were gradual, with the language faculty evolving gradually by small increments, one grammatical principle at a time. (Pinker and Bloom further assumed that the principal function served by language is "the communication of propositional structures over a serial channel." (p. 713). We return to the issue of what function language serves in the next section.)

Pinker and Bloom's argument about the evolution through natural selection of innate features of language stayed at a quite general level, but other linguists got down to specific details. For several decades, one of the most widely discussed examples of an innate, specifically linguistic principle was the Subjacency Principle. This accounts for the fact that movement of certain linguistic constituents is allowed under some structural conditions but not permitted under other conditions. For instance, fronting of the question word 'who' gives a perfectly grammatical result when applied to the rhetorically incredulous 'Bill believes Mary saw who?' giving 'Who does Bill believe Mary saw?' One might expect that this rule of 'wh-' fronting could apply generally, but if one tries to apply it to the slightly more complex 'Bill believes the claim that Mary saw who?' (a source that is grammatically OK), the result is the ungrammatical '*Who does Bill believe the claim that Mary saw?' Thus this movement rule is restricted in its application to certain structures specified in detail by the Subjacency Principle; this principle handles a range of phenomena other than *wh*-movement. Newmeyer (1991) argued that the Subjacency Principle is adaptive, making language easier to process. Lightfoot, in contrast, argued against the adaptiveness of any innate

principles such as subjacency on the grounds that obeying the subjacency constraint in one's utterances was hardly likely to make any difference in attracting a mate. Lightfoot's position on the evolution of language was in line with the more general views on evolution of S. J. Gould, who stressed the accidental nature of much biological evolution, correspondingly downgrading the systematic role of natural selection. Gould adapted the term 'spandrel' from art history to describe a feature of an organism that is not adapted to any particular function but is merely an accident or a side-effect of some other (possibly adaptive) feature. In Lightfoot's view, innate features of the language faculty are spandrels. In the early 1990s, the debate involved figures such as Pinker and Bloom on the adaptationist side and Chomsky, Lightfoot, and Gould on the nonadaptationist side. The adaptationist side of the argument is in line with the prominent movement called Evolutionary Psychology (Barkow *et al.*, 1992), which holds that much in human psychology is an evolutionary adaptation. Two computer models of this period (Hurford, 1989, 1991) also assumed that certain very basic aspects of language, the arbitrary bidirectional Saussurean sign and the critical period for language acquisition, were the outcome of natural selection and simulated the relevant mechanisms.

During the period in which the innate language faculty was held to be rich in information (i.e., before the Minimalist Program), much skepticism was voiced over whether so much innate information could plausibly have evolved during the relatively brief lifetime of *Homo sapiens sapiens*. Worden (1995), among others, argued that there could not have been enough time for a very rich language acquisition device to have evolved biologically. Nativist linguists were accused of believing in biologically implausible 'macromutations' or of having a saltationist view of evolution. The move to the view that there is in fact much less to the innate language faculty than was previously thought receives a much more sympathetic hearing from biologists. Linguists who are closely familiar with the enormous complexity of real languages, and who believe that it cannot be reduced to minimal principles, face a dilemma: either implausibly attribute all the complexity to biological (possibly adaptive) evolution or find some nonbiological mechanism accounting for the complexity.

The issues of how much of the innate language faculty is special and how much of it is biologically adaptive are intertwined, and positions have shifted in the past decade. **Table 1** outlines the possible positions and names representatives of these positions.

Table 1 Adaptiveness and richness of language structure: theoretical positions

	UG is rich	*UG is minimal*
UG is an adaptive product of natural selection	Pinker & Bloom	
UG is a spandrel, not adaptive	Chomsky before Minimalism, Lightfoot	Chomsky after Minimalism

Adaptation and Function: What Is Language Good For?

Theorists such as Lightfoot and Chomsky, who deny any role for natural selection in the evolution of the special innate structural properties of language, do not deny that language is enormously useful. Once we had got it, it turned out to be useful. We had inherited a fortune, in terms of power to alter the world. This position has sometimes been construed as anti-Darwinian, but in fact, accounting for the particular structures of language in Darwinian terms is by no means a straightforward matter. We survey some prominent ideas below.

A group of ideas about the adaptive function of language can be classified as 'Social.' Dunbar's (1998) theory is based on a correlation between cortex size and social group size and on claims that language first evolved as a form of social grooming. As social groups got larger, there was not enough time for animals to spend time in one-to-one grooming episodes and maintain social bonds with the whole group. A form of language, which allows a speaker to address many hearers at a time, stepped in. Locke (1998) argues that early forms of language were adaptive for purposes of social bonding. Another social theory is that runaway sexual selection helped the evolution of language (Miller, 2000): elaborate linguistic performances attracted mates. None of these theories, as their authors admit, explain the particular complex grammatical and phonological details characteristic of language. Perhaps, however, they can help to explain the very early stages in the evolution of communication.

Another group of theories, which holds more promise for getting to grips with the detailed structure of languages, can be labeled 'Cognitive/Communicative' theories. It seems obvious to most people that the primary function of language is communication. There is a serious problem with accepting the simple view that language evolved for the purpose of communicating complex messages, however. This is the problem of altruism. Information is a valuable resource. How can it benefit an

individual to share information with another? Why, for example, should one animal risk drawing the attention of a predator by issuing an alarm call? Why should one animal tell another where to find food, especially if food is scarce? In most scenarios that one can imagine, no advantage accrues to an individual giving away information for free. (It costs virtually nothing to talk.) The accepted wisdom in biology is that natural selection works at the level of the individual or the gene, but not at the level of the social group. So an argument that language evolved because it benefited groups that possessed it will run afoul of objections from biologists. However, recently Sober and Wilson (1999) have advanced arguments that group selection may after all be a biologically viable mechanism. This opens up the possibility for an evolutionary explanation for language as an instrument of communication.

Chomsky has often argued that the primary function of language is not communication but, rather, internal mental representation (thought). Notice how a view that language is used for communication of facts to other individuals in fact requires the existence in speakers of preexisting internal mental representations. Communication is usually pictured as the transmission of ideas from one head to another, and this presupposes that the ideas must be in the first head to start with. However, although communication requires preexisting internal mental representation, it also imposes further requirements (see Hurford, 2002). There are many features of language (all of phonetics and phonology for a start) that are not required for purposes of thought. We do not think in a particular regional accent. Our thoughts do not exhibit such grammatical features as subject–verb agreement. It seems reasonable that some, but not necessarily all, features of language evolved to suit the purposes of communication.

The suitability of a language to its function can be a result either of the biological adaptation of humans, allowing them to acquire such useful systems, or of the cultural adaptation of the language by humans, tailoring it to suit their communicative purposes. The two options are not mutually exclusive; in fact, both biological and cultural adaptation probably have a role. It need not be supposed that the cultural tailoring of language is in any way intentional or conscious. When it happens, it is as a result of an 'invisible hand' mechanism of the sort proposed by Adam Smith (1776) for economics.

There are several possible pressures that can impinge on the cultural evolution of languages, which one can classify under the headings of the roles people take in relation to language. People are speakers, hearers, and learners. From the selfish point of view of a speaker, economy of effort is important, so there is motivation to slur pronunciation, to truncate sentences, and to use easily retrievable words. This does not help the hearer. From the point of view of the hearer, a message should be clear: its constituent words should be distinctly articulated, its structure should not be ambiguous, and it should not be too cryptically short (nor too long to handle). The pressures on a speaker and a hearer are opposed, and it seems that the behavior of speakers typically ends up as a compromise between these rival pressures.

The behavior of typical speakers is what confronts a newborn child, but the child has an additional problem; namely, learning the particular grammar and lexicon of the language. For language to be learnable, there has to be a way into it that the child can pick up from whatever innate dispositions it is born with. For instance, once a child has learned a small basic vocabulary, it can pick up a lot more by inferring the meanings and grammatical functions (e.g., noun, verb, etc.) of new words from their context. However, if the sentences of a language were structured in such a way that knowledge of the meanings and functions of every word in a sentence was essential to understanding it, then the child could never get a toehold. Such a language would be unlearnable. Clearly, languages have evolved to be learnable.

The view that languages have evolved to be learnable is actually very close to the Chomskyan idea of language universals being attributable to the innate properties of the language learner. No learning is unbiased – there is never any pure *tabula rasa* on which experience stamps an impression – so when we speak of languages evolving to be learnable, we must be thinking in terms of learners with some preexisting bias. Given a strong enough set of initial biases in the language learner, the resulting grammatical systems that can be internalized by the learner are severely constrained. This is another way of saying that languages are selected for learnability. In the Chomskyan version of this story, the adaptation of the language to the learner takes place in a single generation and takes place every generation. But learnability is a matter of degree: some systems are more easily learnable than others. Thus, it is reasonable to envisage a slower process of adaptation to the biases of learners, occurring over many generations. Over the course of history, a language will get to be more learnable, barring invasions from other languages.

In summary, research into the evolution of language is now possible and worthwhile. Evolutionary considerations can help us to make sense of language structure. That being accepted, many of the central

issues in language evolution are also central in (non-evolutionary) linguistic theorizing. For example, how much about language is special? The argument rages, with prominent theorists on both sides. For example, Chomsky entertains the radical idea that the only trait special to human language is recursion, and Jackendoff and Pinker, more traditionally, claim that linguistic behavior is special in many other ways. A closely related question is whether whatever is special to language is adaptive – the outcome of natural selection. Again, argument rages. It is hard to find adaptive evolutionary explanations for many of the more intricate aspects of syntax. A promising alternative to biological selection is cultural selection by successive generations of language learners and language producers of more and more elaborate ('grammaticalized') structures.

Evolutionary Theories of Language: Previous Theories

Ancient and Early Modern Theories

This article will take 'evolutionary' to include any enquiry into the origin of language that assumes it appeared not fully blown, but in some rudimentary form that then developed toward the kind of language we know today. Many of the world's cultures are like that of the Hebrews, in having a nonevolutionary account of language as a divine endowment that separates humans from other animals. Less common is the sort of tradition recorded by Plato in the *Cratylus*, which imagines a purely conventional origin for language as the creation of one or more individuals.

In the first squarely evolutionary theory of language, Epicurus (*Letter to Herodotus*) held that languages originate directly from the body and in a subsequent evolution are refined by social convention. In Epicurus's first stage, the nature of the particular ethnos, itself shaped by race and environment, determines an initial 'rough' language for that people. Although spoken not by reasoning but by natural constraint, this language provides a basis upon which rational thought and social agreement can henceforth be constructed. People can then become aware of the flaws in the language, such as ambiguity or lack of conciseness, and introduce improvements by 'common consent' within the ethnos.

Epicurus's view of language evolution as rooted in ethnic difference stands in stark contrast to the earlier teachings of Aristotle, who took the feelings and impressions experienced by human beings to be universal, "the same for all" (*On interpretation*). But Aristotle could offer no explanation for why different languages should exist. For later Epicureans like Lucretius (*De rerum natura*), the great advantage of Epicurus's theory was its avoidance of what they saw as the absurdity of a conventionalist account of the origin of language, imagining as it does that people could have reached agreement about the meaning of words without already having a language in which to discuss and reach agreement (see further Joseph, 2000: Chapter 4).

The philosophical discourse within which Epicureanism was framed would fall silent in Europe under the dominance of Christian teaching, in which language was not merely created by God but actually one with God Himself (John 1:1). The existence of different languages was explained by the story of Babel, and although there was intellectual space open for inquiring into why different languages might have developed as they did, scholars showed little interest in the differences among languages during the first 1300 years of Christianity.

However, interest in language reemerged with the Renaissance, beginning with the new attention given to the work first of Aristotle, then Plato, then Epicurus, who was made into the precursor of a 'modern' view of language and mind as formed through sensory experience rather than innate endowment. The Epicurean concept of different sounds emitted by animals, according to whether they are experiencing fear, pain, or happiness, would now be designated 'natural signs' and would be the bedrock of modern evolutionary theories of language, offering continuity with other species as well as an explanation of why languages share common features.

Francis Bacon was among the first modern Europeans to take seriously the notion that Chinese character writing represented – or could be adapted to represent – natural signs and physical objects, rather than conventionalized, language-specific signs and concepts, and thereby formed a truly universal language. In the 17th century, various schemes for a 'real character' were launched, notably those by Comenius, Wilkins, and Dalgarno (see Cram and Maat, 2001: 1–74). The spirit of all these schemes – a 'return' to the natural and original language of humans, which had been obfuscated by conventional languages – was implicitly consonant with both the Epicurean and the biblical worldviews. As such, it both supported and received support from a Protestant ideology that wanted to clear the decks of religious worship from conventional accretions piled on by a Rome that, as it happened, had spent the last five centuries in the intellectual thrall of Aristotle.

The 18th Century

The 'long 18th century' in the discussion of linguistic evolution started with the publication in 1690 of Locke's *Essay on human understanding*. Locke broke understanding down into elemental 'ideas' that joined in various ways to form more complex ones, and held that, because these ideas were transmitted to us and retained by us via words, the regulation of language was the key to improving human understanding. The first decades of the 18th century saw numerous attempts to link Locke's analysis to the development of language, for example by Vico and Warburton. But it was a French cleric, the Abbot of Condillac, who turned Locke's scheme into the most influential of early modern evolutionary theories of language. His 1746 *Essai sur l'origine des connaissances humaines* asserted that language originated with simple signs in the form of 'natural' cries and bodily signals. The crucial change occurred when this 'language of action,' atemporal and synthetic, evolved into conventional language, which was successive, signifying in bits spread across time: The sounds made up the word, the words made up the sentence, and the sentences made up the discourse. Both in the species and in the individual, it was the acquisition of conventional language that made thought itself temporal and analytical.

Reactions to Condillac were quick and widespread. Adam Smith contested the possibility that change in a language represented any kind of progress for those who spoke it. Rather, language evolution enacted a different kind of structural economy, where a shift from simplicity toward compoundedness followed necessarily from the movement of populations and provoked an equal and opposite shift within another area of language structure. Also in 1761, Rousseau completed his remarkable *Essai sur l'origine des*

langues (not published until 1781). Contrary to Condillac, he insisted that although "needs dictated the first gestures, [. . .] the passions drew out the first words," which in fact must have been sung, since accents, tones, and rhythm were the features of language that issued naturally from the throats of infants. These features continued to predominate in the 'southern' language type, represented by Chinese and Arabic, which were also more natural in the prominence they give to vowels. Consonants – an intrusion of the analytical – had spread with phonetic writing, first in the northern languages and only latterly to the southern. Moreover, the original language consisted entirely of tropes, images, and other forms of figurative speech, with the force of onomatopoeia felt continually. Again, wrote Rousseau, these continued to be more characteristic of the southern language type than the northern.

The *Abhandlung über den Ursprung der Sprache* by Herder won the Berlin Academy Prize in 1770 and was much more widely read than Rousseau's *Essai*. Herder positioned himself in opposition to both Condillac and Rousseau by asserting that "the former turned animals into men and the latter men into animals." He rejected any attempt to draw an analogy from the 'naturalness' of animal language to human language. Human language was invented once man was "placed in the state of reflection which is peculiar to him" and when the mind in this state of reflection was "for the first time given full freedom of action." Neither this reflection nor this freedom was shared by animals, whereas for humans they were "essential to his species; and so is language."

The 18th century was the great age of evolutionary theories of language, producing them in too great an abundance to be covered adequately here; a somewhat fuller summary can be found in Rée (1999: Chapter 12).

The 19th Century

As the 19th century progressed, academic attention focused ever more closely on details of linguistic form and their history relative to one another, rather than the construction of grand narratives of origins. Two main impulses emerged, one of which was to classify all the languages of the world in a way that would help identify the essential type that each represented, and how the types fundamentally differed from one another. This impulse was memorably developed by Humboldt, who in a treatise published posthumously in 1836, insisted that the intellectual power of a language was determined more by its purity within its type (isolating, agglutinating, or inflectional) than by the type itself. Like Herder, Humboldt started from the Romantic assumption that the whole history of a language is already contained in germ in its origin – its evolution is actually just the unfolding of these preordained developments.

The other impulse was to understand the historical affiliations of the classical languages to one another and to those other highly inflected European and Southwest Asian languages with which they were plausibly related within a relatively shallow time depth. Bopp (1857–61) took the Indo–European proto-language to have a relatively simple structure that became more complex with subsequent evolution. But by the time of Schleicher (1869), the ideology had become one in which every structural feature of every Indo–European language had to be explicable by features already present in the proto-language. The result was that the individual languages no longer appeared as more complex versions of that original state but simplifications from it, implying a very different evolutionary process indeed.

Schleicher is also remembered for his insistence that language was an organism – his introduction of the 'family tree' schema for linguistic evolution was not originally metaphorical in intent, because he really conceived of the growth of languages and of trees as two instances of the same process – for his insistence that in historical times, languages were necessarily in decay, characterizing contemporary languages as 'senile relics' of their glorious forebears (a view that would be forcefully contested by Jespersen, 1894); and for the influence of his writings on Haeckel, who sent a copy of Schleicher's 1863 book (translated into English in 1869) to Huxley, a disciple of Darwin. Darwin was critical of historical linguists who worked with a model of slow, gradual evolution that was naturalistic in the sense of being wholly internally determined; biological evolution, as he saw it, demanded sharper, environmentally sensitive changes. Alter (1999) provided a rich account of the interchanges among these figures, as well as the bitter debate between, on one side, Max Müller, and on the other, Darwin and Whitney (see also Koerner, 1983).

One other position on the evolution of language that rose to prominence in the latter part of the 19th century, harked back to the 17th and early 18th centuries. This was the view that the natural signs with which language originated could be observed in the present in the manual sign languages of deaf-mutes and certain 'primitive' peoples. The person chiefly responsible for thrusting this idea back into the limelight was E. B. Tylor, the first professor of anthropology at Oxford. Tylor made much of the research on American Indian sign languages conducted by Mallery, and in turn Mallery and J. W. Powell wrote extensively in support of Tylor's theory

(see Rée, 1999: Chapter 24). It helped promote the general view that continued to inform anthropology at least into the 1920s, that observing primitive peoples and their languages offered a look into earlier phases of human evolution.

The 20th Century

As with the 18th century, a slightly 'long' 20th century of linguistic evolutionary theory can be dated from just before the turn of the century, with the publication of Jespersen (1894) and Baldwin (1896). Baldwin argued that an evolutionarily advantageous factor need not arise by chance mutation but could be produced by deliberate invention and cultural propagation, after which the advantage it conferred might henceforth become a part of genetic human evolution. The Baldwin factor liberated evolutionary accounts of language from bondage to naturalistic origin theories. Yet linguists had by this time so focused their attention onto details of sound change that it was only in Baldwin's own field of psychology that the full impact of his proposal was realized (although since the late 1980s, when linguists rediscovered language evolution as a topic of inquiry, the 'Baldwin effect' has been at the center of the discourse).

Otherwise, the first half of the 20th century was a decadent period for evolutionary theories of language. The rise of structuralism and behaviorism meant a shift away from historical inquiry and onto a specific focus on how language systems worked or how speakers performed linguistically. Jespersen continued to put forward his strong modernist view that language change represented a form of evolutionary progress, a sentiment shared by most linguists. However, there were occasional bursts of new, or at least seminovel, evolutionary theories, the most spectacular of which was the 'Japhetic' theory of Marr, which became the official Soviet theory of language in the 1930s. Marr believed in an original cultural and linguistic unity spanning most of the world and introduced a 'paleontological analysis' that reduced all the words of all languages to four basic elements – *sal, ber, yon,* and *rosh* – occurring singly or in combination. He analyzed their subsequent history according to his theory of 'stadialism,' which held that economic revolution must produce linguistic evolution. Outside the Soviet Union, and eventually inside as well, Marr's theories were dismissed as methodologically unsound and ideologically driven.

Paget (1930) put forward an account of the evolution of language, starting from 'mouth-gestures' that he had analyzed in Polynesian languages. Rudolf Steiner developed a similar tongue–gesture theory, without the empirical support but with a spiritual dimension that had great appeal for the semimystical Nazi philosophy that was taking root in the 1920s and 1930s. This philosophy became bound up with a belief in Aryan origins that historical linguistic research appeared to support (see Hutton, 1999). The eugenic and genocidal horrors that ensued were sufficient (along with the methodological shifts already described) to quell interest in evolutionary theories of language after World War II. The forms such theories took following the eventual resurrection of interest in the topic are described in a separate article (*see* **Evolutionary Theories of Language: Current Theories**).

Ewe

J Essegbey, University of Florida, Gainesville, FL, USA

© 2006 Elsevier Ltd. All rights reserved.

Also written Eʋe, and pronounced /əβə/, Ewe designates a dialect cluster that is spoken mainly in Southeastern Ghana, but also in the southern part of Togo and across the Togo-Benin border. Its dialects include Kpele and Notsie, spoken in Togo, Waci, spoken in Benin, and Aŋlɔ, Tɔŋu, Ho, Kpedze, Anfoe, and Kpandu, all spoken in Ghana. The dialects in Ghana are grouped into Coastal (e.g., Aŋlɔ, Tɔŋu), Central (e.g., Ho, Kpedze), and Northern (e.g., Anfoe, Kpando). The Central and Northern dialects are also grouped together as Inland dialects. Ewe is part of the Gbe language cluster (cf. Capo, 1991), which belongs to the Kwa family.

History and Sociolinguistics

The origin of the Gbe-speaking people has been traced to Ketu, a Yoruba town in the present-day Benin. From there they moved southward, with some founding a settlement at Tado, while others settled at Adele and others went to Notsie. The Ewes are among those who settled in Notsie. They say that their forefathers fled the tyranny of a ruler of Notsie called Agorkoli, and dispersed to their present-day locations.

Ewe is spoken by approximately 3–5 million speakers. It is taught as a subject from elementary school to the university level and is one of the seven national languages in the media in Ghana, and one of two in Togo. A clear dialectal difference can be established between the Coastal and Inland dialects, e.g., 'ash' is *afi* in the Coastal dialects, and *dzowɔ* in the Inland. The former also have a habitual suffix *-na*, which is represented in the other dialects as -V, the resultant realization being determined by the preceding vowel. Hence *zɔna* 'walks' is *zɔɔ* in the Inland while *fena* 'plays' is *feɛ*.

In addition, the initiator of greetings at the Coast exhausts all his or her questions before the interlocutor begins. By contrast, in the inland, both speakers take turns in asking how-are-you questions. Left-hand use is prohibited in social interaction, giving rise to interesting modes of pointing.

Phonology

Ewe has 29 consonants and seven oral vowels with nasalized counterparts. Notable among the consonants are labiovelar stops, bilabial fricatives, and a velar approximant. Both /l/ and /r/ occur in complementary distribution: /r/ occurs before laminodentals, alveolars, and palatals, while /l/ occurs elsewhere, including in word-initial position. Also, /w/ occurs before rounded vowels while /ɣ/ occurs before unrounded vowels (*wɔ* 'do' vs. *ɣi* 'white'). Although most of the dialects have all the nasalized vowels, a few, including Peki, do not have /õ/. Thus instead of *lõ* 'take off fire,' they say *lɔ̃*.

Ewe

J Essegbey, University of Florida, Gainesville, FL, USA

© 2006 Elsevier Ltd. All rights reserved.

Also written Eʋe, and pronounced /əβə/, Ewe designates a dialect cluster that is spoken mainly in Southeastern Ghana, but also in the southern part of Togo and across the Togo-Benin border. Its dialects include Kpele and Notsie, spoken in Togo, Waci, spoken in Benin, and Aŋlɔ, Tɔŋu, Ho, Kpedze, Anfoe, and Kpandu, all spoken in Ghana. The dialects in Ghana are grouped into Coastal (e.g., Aŋlɔ, Tɔŋu), Central (e.g., Ho, Kpedze), and Northern (e.g., Anfoe, Kpando). The Central and Northern dialects are also grouped together as Inland dialects. Ewe is part of the Gbe language cluster (cf. Capo, 1991), which belongs to the Kwa family.

History and Sociolinguistics

The origin of the Gbe-speaking people has been traced to Ketu, a Yoruba town in the present-day Benin. From there they moved southward, with some founding a settlement at Tado, while others settled at Adele and others went to Notsie. The Ewes are among those who settled in Notsie. They say that their forefathers fled the tyranny of a ruler of Notsie called Agorkoli, and dispersed to their present-day locations.

Ewe is spoken by approximately 3–5 million speakers. It is taught as a subject from elementary school to the university level and is one of the seven national languages in the media in Ghana, and one of two in Togo. A clear dialectal difference can be established between the Coastal and Inland dialects, e.g., 'ash' is *afi* in the Coastal dialects, and *dzowɔ* in the Inland. The former also have a habitual suffix *-na*, which is represented in the other dialects as -V, the resultant realization being determined by the preceding vowel. Hence *zɔna* 'walks' is *zɔɔ* in the Inland while *fena* 'plays' is *feɛ*.

In addition, the initiator of greetings at the Coast exhausts all his or her questions before the interlocutor begins. By contrast, in the inland, both speakers take turns in asking how-are-you questions. Left-hand use is prohibited in social interaction, giving rise to interesting modes of pointing.

Phonology

Ewe has 29 consonants and seven oral vowels with nasalized counterparts. Notable among the consonants are labiovelar stops, bilabial fricatives, and a velar approximant. Both /l/ and /r/ occur in complementary distribution: /r/ occurs before laminodentals, alveolars, and palatals, while /l/ occurs elsewhere, including in word-initial position. Also, /w/ occurs before rounded vowels while /ɣ/ occurs before unrounded vowels (*wɔ* 'do' vs. *ɣi* 'white'). Although most of the dialects have all the nasalized vowels, a few, including Peki, do not have /õ/. Thus instead of *lõ* 'take off fire,' they say *lɔ̃*.

Ewe is a tone language. Phonetically, all the dialects have high, mid, and low tones, which also combine to yield six contour tones. Phonologically, it has a high and nonhigh tone, both of which are dependent on the environment. Thus nonhigh tone is realized as mid in a root noun that has a voiceless obstruent or sonorant, and low before a voiced obstruent. High tone is realized as high before a voiceless obstruent and mid before a voiced obstruent. Aŋlɔ also has a phonologically conditioned extrahigh tone, while Adangbe has an extralow tone that occurs on the utterance-final interrogative particle.

The syllable structure is mainly open, although a few words end with nasals, e.g., *kpam* 'sound of slap.' While it is possible to have a maximum of two syllable-initial consonants, the second has to be a liquid or approximant. The nucleus can be a vowel or a nasal.

Morphology

Ewe has been characterized as an isolating language with agglutinating features (Ameka, 1991). Thus, many words look like a concatenation of individual morphemes:

nyɔnu-vi-wo
woman-little-PL
'girls'

It has only one inflectional affix, i.e., the habitual suffix *-na*. However, it has derivational processes, which include reduplication, triplication, and compounding. It also has derivational affixes such as the agentive *la*:

nu-fia-la
[thing-teach-AG]
teacher

Syntax

Syntactically, Ewe is an SVO language, with alternative OSV order being determined by semantic and pragmatic factors such as topicalization and focusing. Within the noun phrase, modifiers follow the head noun (*ɖevi nyui la* 'child good the'). The plural morpheme *wo* is related to the third person plural pronoun *wo* and is not required when the NP has a numeral (*ɖeviwo* 'children' vs. *ɖevi eve* 'two children'). It is, however, obligatory after a determiner (*ɖevi eve ma-*(wo)* 'child two that-PL'). There is a logophoric pronoun (*ye*) that occurs in a subordinate clause introduced by *be(na)* 'that' (cf. Clements, 1979; Essegbey, 1994).

Ewe is a tenseless language. An active verb in the aorist receives past tense interpretation, (*e-ɖu nu* 'he ate'), while a stative or inchoative verb receives present tense interpretation (*e-ku* 'it is dead'). A potential morpheme gives rise to future interpretation. It has a serial verb construction (SVC) in which the two or more verbs in a clause share the same TMA value. Negation in the clause is a discontinuous morpheme *me . . . o*: *me* precedes the first verb and *o* occurs at the end of the clause. Ewe has obligatory complement verbs (OCVs): verbs with fully specified meaning have to take a generic-meaning complement (*ɖu nu* 'eat thing'), while others with less determined meanings have their meaning further specified by the complement. These are known as inherent complement verbs (ICVs), (*fu tsi* 'move_limb water = swim').

There are two types of double object constructions: Theme-Goal (*bia nya Kofi*, literally 'ask word Kofi') and Goal-Theme (*na Kofi ga* 'give Kofi'). *Na* 'give' and *fia* 'teach' occur in both constructions. Finally, Ewe has ideophones, some of which code manner of motion concepts, e.g., *dziadzia* 'energetic walking.'

Existence

B Caplan, University of Manitoba, Winnipeg, Canada

© 2006 Elsevier Ltd. All rights reserved.

What Existence Is

Existence is the property that is attributed to Uma Thurman in

(1) Uma Thurman exists.

Perhaps existence is also attributed to some object in

(2) There is an even prime.

There is a connection between existence and (objectual) quantification: what exists is exactly what our quantifiers quantify over, when our quantifiers are unrestricted. Sometimes our quantifiers are restricted so that they quantify over only some of the things that exist. For example, in

(3) All the bottles of beer are in the fridge.

the quantifier "all the bottles of beer" is naturally interpreted so that it doesn't quantify over **all** of the bottles of beer in existence. But what exists is not limited to what our quantifiers quantify over when they are restricted in one way or another. (In various free logics, variables need not be interpreted so as to have as values objects that exist. Sometimes a special predicate is introduced for 'exists' in these logics. Existence is not tied to quantification in these logics, although it might be tied to the special predicate.)

It seems that existence is a property that everything has: namely, the property *existing* or *being existent*. But various philosophers deny this for various reasons: some deny that existence is a property; others accept that existence is a property but deny that any objects have it (because only properties do); and still others accept that existence is a property but deny that all objects have it (because only some do).

The Hume-Kant View

The Scottish philosopher David Hume (1711–1776) and the German philosopher Immanuel Kant (1724–1804) denied that existence is a property. (It is often said that existence is not a predicate. This is at best a confused way of denying that existence is a property.) Let us call the view that existence is not a property the *Hume-Kant view*. One reason for holding the Hume-Kant view is that existence is supposedly not a property but rather a precondition for having properties. After all, how could something have any properties if it did not exist? But it is hard to see what a precondition is if it is not a property. For example, being human might be a precondition for being a movie star; and *being human* is a property.

Another reason for holding the Hume-Kant view is that to say that something has a property **F** and exists is supposedly not to say anything more than that something has **F**. For example,

(4) Uma is a movie star and exists.

supposedly doesn't say anything more than

(5) Uma is a movie star.

But if this is a good reason to deny that existence is a property, then it is also a good reason to deny that *being self-identical* or *being either round or not round* is a property. For if (4) doesn't say anything more than (5), then

(6) Uma is a movie star and is self-identical.

and

(7) Uma is a movie star and is either round or not round.

don't say anything more than (5) either. But it seems that *being self-identical* and *being either round or not round* are perfectly respectable properties. For example, *being round* is a perfectly respectable property. And if negations and disjunctions of perfectly respectable properties are themselves perfectly respectable properties, then *being either round or not round* is also a perfectly respectable property.

The Frege-Russell View

Some philosophers who accept that existence is a property deny that everything has it, because they think that no ***objects*** have it; rather, they think that only *properties* have it. On this view, *existence is* not a (first-level) property of objects; rather, it is a (higher-level) property of properties. In particular, it is the property *being instantiated*. This is a view that was held by the German mathematician and philosopher Gottlob Frege (1848–1925) and, at least at one time, by the British philosopher Bertrand Russell (1872–1970). Let's call this view the *Frege-Russell view*.

One reason for holding the Frege-Russell view is that if existence were a property of objects, then it would not be possible to be mistaken in ascribing that property to an object. (By contrast, one can attribute the property *being instantiated* to the property *being a golden mountain*, say, even if that property is

not instantiated.) But if this is a good reason to deny that existence is a property of objects, then it is also a good reason to deny that *being self-identical* or *being either round or not round* is a property of objects. For it is not possible to be mistaken in ascribing those properties to an object either. And yet they are perfectly respectable properties of objects.

Another reason for holding the Frege-Russell view comes from the problem of negative existentials. A *negative existential* is a sentence like

(8) The golden mountain doesn't exist.

which seems to say of some object that it doesn't exist. For example, (8) seems to say, of the object that "the golden mountain" refers to, that it doesn't exist. Either "the golden mountain" refers to something or it doesn't. On the one hand, if "the golden mountain" doesn't refer to anything, then it seems that (8) doesn't say anything about anything. On the other hand, if "the golden mountain" does refer to something, then it seems that it must refer to something that exists, in which case (8) says, of something that does exist, that it doesn't exist. Either way, it seems that (8) can't be true. But (8) seems true; hence the problem.

The Frege-Russell view offers a straightforward solution to the problem of negative existentials. On the Frege-Russell view, (8) says, of the property *being the golden mountain*, that it does not have the property *being instantiated*. And it is true that the property *being the golden mountain* does not have the property *being instantiated*. So, on the Frege-Russell view, (8) is true, as desired. (Russell's treatment of definite descriptions like "the golden mountain" is actually more complicated. (*see* **Descriptions, Definite and Indefinite: Philosophical Aspects**). One might worry that even if Russell's treatment solved the problem of negative existentials for sentences like (8), it wouldn't solve the problem of negative existentials for sentences like

(9) Santa Claus doesn't exist.

which contain names rather than definite descriptions (*see* **Proper Names: Philosophical Aspects**).

One problem with the Frege-Russell view is that (8) doesn't seem to say the same thing as

(10) The property *being the golden mountain* doesn't have the property *being instantiated*.

Similarly,

(11) If the golden mountain were to exist and if cows were to fly, then just as they would have the property *being able to fly*, it would have the property *being golden*.

seems true, and it doesn't seem to say the same thing as

(12) If the property *being the golden mountain* were to have the property *being instantiated* and if cows were to fly, then just as they would have the property *being able to fly*, it would be instantiated by something that has the property *being golden*.

Another problem with the Frege-Russell view is that the property *being instantiated* doesn't seem to be fundamental in the right sort of way. It seems that facts about which properties have the property *being instantiated* depend on quantificational facts. For example, it seems that the property *being a movie star* has the property *being instantiated* only because some object (Uma, say) instantiates the property *being a movie star*. But it seems that objects (Uma, say) can instantiate properties (*being a movie star*, say) only if they exist. So if it is to be instantiated, then the property *being instantiated* seems to require that some objects exist and hence that, contrary to the Frege-Russell view, existence be a property that at least some objects have.

The Meinong-Russell View

Some philosophers who accept that existence is a property deny that everything has it, because they think that some, but not all, objects have it. At one time, Russell thought that there is a broad ontological property that everything has; but he thought that this property is *being* (or *subsisting*), not *existing*. On this view, the golden mountain, the round square, numbers, sets, tables, and chairs have being; but only tables and chairs (and other objects that are located in space and time) exist. The Austrian philosopher Alexius Meinong (1853–1920) held a similar view. He thought that there is a broad ontological property that everything has; but he thought that this property is *being an object*, not *being* or *existing*. On this view, the golden mountain, the round square, numbers, sets, tables, and chairs are objects; but of these, only numbers, sets, tables, and chairs have being. (And only tables, chairs, and other objects that are located in space and time exist.) Let's call this – the view that although there is a broad ontological property that everything has, only some objects exist – the *Meinong-Russell view*.

One reason for holding the Meinong-Russell view is that it offers a straightforward solution to the problem of negative existentials. On the Meinong-Russell view, (8) says, of the object "the golden mountain" refers to, that it doesn't exist, and "the golden mountain" refers to an object that doesn't exist. So, on the Meinong-Russell view, (8) is true, as desired.

But the Meinong-Russell view doesn't solve parallel problems. A *negative subsistential* is a sentence like

(13) The golden mountain has no being.

that seems to say of some object that it has no being. Those who distinguish being and existence sometimes say that "there is" has to do with being, not existence. On this view,

(14) There is no golden mountain.

is also a negative subsistential. And a *negative objectual* is a sentence like

(15) The golden mountain isn't an object.

or

(16) No object is the golden mountain.

that seems to say of some object that it isn't an object. Speakers who have the intuition that (8) is true might also have the intuition that (13)–(16) are true. And if a solution to the problem of negative existentials should respect speakers' intuition that (8) is true, then one might think that a solution to the problem of negative subsistentials or negative objectuals should similarly respect speakers' intuition about (13)–(16). But on the Meinong-Russell view, (13) and (14) or at least (15) and (16) are false, because "the golden mountain" refers to an object that has being or at least is an object. (This argument might work best against those who say that (8) is false but (14) is true.) Solving the problem of negative existentials only at the cost of not solving the problem of negative subsistentials or the problem of negative objectuals doesn't seem like much of a benefit. In addition, many dislike the Meinong-Russell view because, by saying that existence is what Russell (1903) once called "the prerogative of some only amongst beings," the view offends what Russell (1919) later described as "a robust sense of reality."

If one rejects the Hume-Kant view, the Frege-Russell view, and the Meinong-Russell view, one is left with the view that existence is a property that everything has. Although there is much to commend this view, those who hold it still have to solve the problem of negative existentials. This suggests that a solution to that problem will not come from views about existence. And once one had a solution to the problem of negative existentials (whatever that solution is and wherever it comes from), it seems that there would be little to prevent one from holding the view that existence is a property that everything has.

Experimental and Instrumental Phonetics: History

H G Tillmann, Institut für Phonetik und Sprachliche Kommunikation, Munich, Germany

© 2006 Elsevier Ltd. All rights reserved.

In the middle of the 19th century in Europe, Ernst von Brücke in Austria (*see* **Brücke, Ernst (1819–1891)**) and Alexander Melville Bell in England (*see* **Bell, Alexander Melville (1819–1905)**) published their proposals for a systematic description of speech sounds on the basis of a new physiology of speech ('sound physiology'). Brücke's (1849, 1856) and Bell's discoveries (1863, 1867) formed part of the development of a new, scientifically based discipline for the investigation of spoken language. This had more than one reason, as will become apparent below. One of these reasons needs to be mentioned immediately, however, since it also gave rise to the academic name of the new discipline.

The word 'phonetic' seems to have been used for the first time in the modern sense in 1797 by the Danish Egyptologist George Zoega. In his dissertation *De origine et usu obeliscorum* published in Rome, he used the adjective *phoneticus* in connection with the question as to what sound forms in ancient Egypt the hieroglyphic signs on the obelisks stood for. The term was established in Europe 25 years later when Champollion (*see* **Champollion, Jean-Francois (1790–1832)**) succeeded in deciphering the hieroglyphic writing system. His solution concerning *l'alphabet des hiéroglyphes phonétiques employés par les Égyptiens* was a sensation, and more and more authors in Europe who dealt with the spoken form of languages and at the same time wanted to stress the specific differences between the spoken and written forms of languages decided to use the adjective 'phonetic' in the new sense.

Early modern speech science had four important sources: the academic development of historical linguistics and comparative philology, both themselves embedded in the evolution of modern sciences, especially the natural sciences; a new public interest in the distinction between written and spoken language, which was motivated in particular by the increasing attention given to the learning and teaching of foreign languages; the cultural need for orthographic reform and standardization of writing, especially true at that time of German and English; and finally the politically and economically inspired interest in developing orthographies for still unwritten languages in the new colonies (*see* **Phonetic Transcription: History**).

Early Discoveries, Assumptions, and New Questions

The rise of modern phonetics as an academic discipline is closely associated with publications by Brücke and Alexander Melville Bell (*see* **Brücke, Ernst (1819–1891), Bell, Alexander Melville (1819–1905)**) confirming what many earlier writers had suggested, (though without the same background of knowledge of the physiology of speech), namely that the alphabetic units of writing could be related in a very systematic way to certain observable properties of the articulatory production of speech. Speech science started as sound physiology and was based on a method called 'direct observation.' It was assumed that the phonetic value of any given alphabetic unit could be unambiguously determined by looking at the articulatory speech organs during the pronunciation of these units. Moreover, 'direct observation' was not restricted to single speech sounds but also meant the visual, auditory, and tactile inspection of whole running speech acts.

Sound Physiology and Articulatory Phonetics

Observable Alphabetic Units: Letters and Sounds Before precise phonetic terms and concepts had become established, such a simple distinction as that between letters and sounds was not at all a trivial one, even for professional linguists. Jacob Grimm (*see* **Grimm, Jacob Ludwig Carl (1785–1863)**), for instance, entitled the first chapter of his famous German Grammar (1822) *Die Lehre von den Buchstaben* (theory of letters), and here the term *letter* meant both the printable form of a letter and also the sound it stands for when used in a text. It should be mentioned that Grimm changed the title of the first chapter for the third edition, 1840, into 'Lautlehre' (theory of sounds). (For an account of early uses of the term 'letter' in English and in other languages, see Abercrombie, 1965.)

Letters were generally understood as names of speech sounds. However, the sounds of fluent speech in running speech acts disappear again at the very moment that they are created by the speaker. Thus the text of an utterance which could be written down from left to right in the form of a linear sequence of alphabetic units seemed to early phoneticians to be the only durable object of observation for scientific investigation. Thus they never called into question the existence of alphabetic units as such.

Naive Assumptions About Letters and Sounds: A Basic Postulate and Two Presuppositions The

theoretical argumentation in Brücke (1856) is very explicit on this point. All letters of a good orthography that is in agreement with pronunciation should be signs that represent real sounds. Sounds constitute the values of an alphabetic sign just as numbers are the value of figures. Brücke was able to propose a new method for characterizing the sound value of given speech sounds. "The time has come," he writes, "to present the 'natural value' of speech sounds and to explain the 'natural connection' between the sounds and their signs. The value of a given sound is determined by its properties which are called 'attributes'." Here it is of interest to note that Brücke distinguishes two different ways of finding the attributes of given sounds: one possibility is to look at the sounds (represented by letters) to see "how they affect their neighboring sounds, and how they are themselves affected by these," and one can also "follow the changes they suffer during the course of time and through their going over from one language into another [...]. This is the way of the linguist" (1856: 1). A different possibility is given by the method of direct observation which "is the way of the physiologist": direct inspection of the production of speech sounds and experiments concerning "the manner and condition of their formation" lead to the desired attributes.

Here the first fundamental postulate of early speech science can be stated. It consisted in the naive assumption that single speech sounds do exist in reality, as alphabetical elements. The nature of this reality was not questioned, simply because it was taken for granted that any given speech sound could be represented by a proper alphabetic symbol. Speech research was mainly devoted to the single aim of determining the relevant attributes, such that alphabetical elements with identical attributes could be represented by just one proper symbol.

This postulate had two presuppositions. It was assumed, first, that speech could be exhaustively investigated as a purely mechanical process, and secondly that the listener could be replaced by a deaf observer. Both these presuppositions can be clearly confirmed in the works of Brücke and Bell.

A Purely Mechanistic Approach Brücke developed his theory of sound physiology with explicit references to earlier pioneers of speech research, two of whom must be mentioned here: Wolfgang von Kempelen (*see* **Kempelen, Wolfgang von (1734–1804)**) with respect to the production of consonants, and Robert Willis with respect to the formation of vowels. After many years of work, von Kempelen was the first to succeed in constructing a mechanical system for synthesizing artificial speech. A native speaker of Hungarian, he worked at the court in Vienna where in 1791 he published his famous book about the mechanism of human language including the description of his speaking machine. Brücke admired this marvelous work (facsimile reprinted in Kempelen, 1970) and prized it as "one of the best physiological books" he knew, and he recommended that all those linguists should read it who "want to make themselves thoroughly acquainted with the purely mechanical part of sound theory" (Willis, 1830: 6). Whereas linguists at that time still tended to use more or less metaphorical expressions in their characterizations of speech sounds (Grimm, for instance, called consonants the "bones and skeleton" and vowels the "blood of the organism" of a language), Brücke insisted on reducing the "wondrous mechanism outpouring the stream of speech" to the physical laws which determine the mechanical structure and function of the human speech organs. He probably saw and heard a model of von Kempelen's speaking machine, which many years later was moved from Vienna to Munich, where it can still be found in the archives of the German Museum.

How von Kempelen succeeded in the acoustic modeling of human sound production has been described in Dudley and Tarnoczy (1950). From a purely mechanical point of view, his speaking machine is a simplified copy of the human speech organs in the form of an instrument that can be manipulated by two hands and the right forearm. As shown in Figure 1, it consists of bellows and a box containing the speech sound articulating system.

The box has two circular windows for inserting the right and left hands (Figure 2). Those who only know the speaking machine from the drawings (as, for instance, in Dudley and Tarnoczy, 1950) will be surprised how small the speech sound articulation system actually is. It has the dimensions of the

Figure 1 "For a speaking machine no more is required," thought von Kempelen (1791: 398), "than a lung, a glottis, and a mouth."

Figure 2 ''Speech or articulation is nothing more than the passage of voice through various openings'' (von Kempelen, p. 397).

human vocal tract. As soon as the right forearm pushes the bellows, which are pulled up by the weight of an iron ball, a rather high, croaky (female) phonation sound is heard. The left hand can be used to open and close the artificial mouth or to perform different degrees of mouth opening for the production of different vowel-like sounds. As Brücke pointed out, the resulting vowels were not very convincing, mainly because the principles discovered by Willis (1830) were not yet known to von Kempelen (cf. 'Acoustic Nature of Speech Sounds' below). With the fingers of the right hand, one could push different levers to produce audible fricatives within the artificial mouth. Two small artificial nostrils could be opened or closed to produce nasal or oral sounds. von Kempelen himself was sufficiently trained to be able to play his instrument in such a way that listeners could recognize single Hungarian and German words.

That von Kempelen, who traveled through Europe to present his sensational speaking machine to paying audiences, was obviously so successful in producing audible events that his listeners could perceive as spoken words simply because he always told his audiences in advance which words they were going to hear next. So von Kempelen not only invented a mechanical speech synthesis system but also what could be called the Von-Kempelen-Principle, which says that any speech synthesis system works much better as soon as top-down processes become dominant as opposed to a situation where speech recognition is restricted to bottom up processes only.

There exists now a complete reconstruction of this mechanical speaking machine (in the F. Kempelen Speech Research Laboratory of the Research Institute for Linguistics in Budapest). This replication is described in Nikléczy and Olaszy (2002). Today there is a new interest in von-Kempelen-type speaking machines in robotics (Gósy, in press). Such a purely mechanical speech production system, which creates the air needed for voice generation by a small pump, imitates the human vocal tract and controls its cross-sectional area function by stepper motors has been developed recently in Japan (Department of Intelligent Mechanical Systems Engineering, KAGAWA University).

The general conclusion that was drawn from the possibility, in principle, of constructing an artificial speaking machine was that human speech could be explained and also wholly described as a purely mechanical process. This is the first presupposition, referred to earlier, underlying the postulate of the direct observability of given speech sounds, and this was also the central theoretical assumption made by Carl Merkel (1812–1876) when he systematically collated current anatomical and physiological knowledge about the "human voice and speech organs" in his *Anthropophonik* (Merkel, 1857).

Speech Sounds as Visible Units The second presupposition of the postulate had to do with the observation that all the different, individual speech articulating systems could be reduced to one generalized abstract mechanical system consisting of certain parts in a particular configuration. Each individual speaker must make use of his lips, his tongue, his velum, etc. in a certain way in order to produce a certain speech sound, and conversely each given speech sound can be analyzed into certain individual actions of certain parts of the generalized system. For the early sound physiologists, it was a very surprising discovery that all possible speech sounds could be compared with each other in relation to such a generalized system and thereby exhaustively analyzed into a set of identical or different articulatory components. The nasals [m, n, ŋ], for instance, share with the stop consonants [b, d, g] their respective place of articulation as well as their articulatory organ, but these two sets of sounds are distinguished from one another by their respective manner of articulation: [m, n, ŋ] are produced with closed mouth passage and open nasal passage (lowered velum), while for [b, d, g], in addition to the mouth closure, the velum is raised to close the nasal passage, which is a necessary condition for the articulation of any plosive (including, of course, the corresponding voiceless ones: [p, t, k]).

It must be emphasized that this possibility of analyzing articulated speech sounds was known over 2000 years earlier to the ancient Indian phoneticians, and to many later investigators of speech in the West. Brücke himself was familiar with the Spanish tradition of language teaching to the deaf, dating back to the 16th century, and mentions Pietro Ponce, a

Benedictine monk who died in 1584. In the Vienna court library, Brücke had discovered a work of a successor of Ponce, Bonet (1620), "the oldest work on teaching the deaf we have" (Brücke, 1856: 15). He also knew the *Tractatus grammatico-physicus de loquela* (1653) of John Wallis (*see* **Wallis, John (1616–1703)**) who began to teach two deaf pupils in England 100 years after the Spanish pioneers. So the original contribution of the sound physiologists to speech science was not that they discovered articulatory phonetics, but rather that they drew systematic conclusions from the earlier discoveries. Their discovery, one may say, was that speech sounds generally can be described from the viewpoint of a deaf observer. Bell clearly indicated in 1867 that this discovery was a central issue for the early speech scientists, when he gave to what can be described as the second standard work of the new speech science the title *Visible speech: universal alphabetics or self-interpreting letters for the writing of all languages in one alphabet*.

The Successful Articulatory Description of Single Speech Sounds Looking back on the early development of speech science it must be recognized that the great successes of articulatory phonetics were mainly restricted to the description of isolated speech sounds. The first sound physiologists did not really look at running speech acts, nor did they investigate concrete, physiological data. They spent most of their time sitting at their desks and observing themselves while repeating the pronunciation of isolated words with a very careful articulation. Thus they discovered very fine distinctions between the different sounds of different languages and gave very reliable articulatory descriptions of possible differences between alphabetically isolatable speech sounds. Tactile perceptions were translated into the visualized model of the articulatory organs.

What the eye could not see directly was, as far as possible, made visible by auxiliary means. As far back as 1803, Erasmus Darwin, grandfather of Charles Darwin, devised a method for investigating the formation of vowel sounds by inserting into the mouth cylinders made of tinfoil which received different impressions according to which vowel was spoken (see Darwin, 1803: 120). Grützner (1879) was the first to experiment with painting the tongue before producing a certain sound in order to look at the colored parts of the hard palate, with the aim of specifying the areas of contact. Oakley Coles (1872), Kingsley (1880, 1887), and Lenz (1888) refined the method of inspecting directly or indirectly produced palatograms to determine the tongue palate contacts of certain sounds. This kind of method is still in use within fieldwork today. Other methods had to be introduced to get a clearer picture of those speech sounds that do not have palatographically illustratable places of articulation. Grandgent (1890, 1892) tried to determine the distance between the tongue and the hard palate. Only a few years later, Atkinson (1899) invented a very delicate instrument for obtaining real mouth-mappings. His method of creating so-called longitudinal stomatograms made use of a thin wire that could be moved within a fixed guiding construction to the point of 'touch-sensation of the tongue' which could then be translated into the drawn picture showing tongue distances from the palate.

Figure 3 "My observations regarding the growth of my hair made it appear prudent to restrict the X-ray recordings to not more than two per week" (Meyer, 1907: 233).

Pictures of the tongue and the hard and soft palate were of special interest in cases where authorities on descriptive phonetics adopted a divergent or even contradictory view about a certain detail. Thus, for instance, Sievers (*see* **Viëtor, Wilhelm (1850–1918)**), Viëtor (*see* **Sweet, Henry (1845–1912)**), and also Sweet agreed in believing that the high front unrounded and rounded German vowels [i] and [y], [e] and [ø] also differ in their tongue height, whereas Jespersen assumed (more from a theoretical point of view) that the only linguistically relevant articulatory difference between these pairs of vowels consisted in their lip position. Here E. A. Meyer – only 10 years after the discovery of the X-rays by Röntgen – was the first to produce very clear radiographic pictures of German vowels and consonants (cf. Figure 3). After having put small leaden plates on the tongue and palate, Meyer exposed himself to X-ray photography.

The exposure time for one single speech sound was about 1 minute (see the quotation in the caption of Figure 3). During this time, the depicted vowel or consonant was reproduced in a fixed steady state, with a duration of about 8 seconds and was repeated between six and eight times. (Meyer was much too optimistic about the safety of X-ray photography – he thought that if the hair of the subject was protected by tinfoil folded many times and if the two sides of the head were each alternately exposed only once a week "any detrimental effect to the body of the subject could be ruled out" (Meyer, 1907: 233).) In his famous contribution to Viëtor's Festschrift, Meyer (1910) proposed another noninvasive method for getting good pictures of the form of the tongue and its distance from the palate: he fixed little threads of nonelastic tinfoil along the midline of an artificial palate and constructed a mechanism for transducing the received tongue impressions into drawn contours.

With these two techniques, Meyer was able to demonstrate that a speaker of northern German did indeed show small but systematic differences in the tongue height during the production of high front rounded and unrounded vowels. As can be gathered from Figure 3, the raising of the tongue during the production of [y] was clearly less than for [i] and nearly as low as for [e]; and the vowel [ø] clearly had a lower tongue position than was found for [e] (cf. (Hoole, 1999)).

The articulatory description of isolated speech sounds is undoubtedly very helpful in the context of teaching the pronunciation of a given language. Anyone who knows how to produce the alphabetic units of a given language in isolation is also in a good starting position for incorporating them in the reproduction of whole words, especially in the clear speech of citation forms. On the other hand, it must be said that the sound physiologists and descriptive phoneticians were never troubled by the fact that alphabetically represented sound structures as found in the citation form of isolated words are subject to more and more reduction in colloquial speech. The reductions and elisions of fluent speech are inconspicuous to the naive observer simply because it is much too complex and runs much too fast for direct observation of it in all its detail. Thus the success of early sound physiology and articulatory phonetics was restricted to the description of more or less careful speech, and especially of the citation forms of isolated words and of single speech sounds uttered in isolation.

An Early Experiment with Isolated Speech Sounds

In 1871, the medical doctor and ear specialist Oskar Wolf published a book entitled *Sprache und Ohr*. He had observed that patients with different degrees and different kinds of hearing losses had different problems in the perception of different speech sounds, and he wanted to know how a normal listener was able to perceive the set of speech sounds he used in testing the hearing abilities of his patients. Thus he was probably the first to conduct an articulation index experiment.

Wolf decided to determine the auditory perceptibility of 18 speech sounds presented partly in isolation, partly in a consonant–vowel context. The alphabetically specified categories of these sounds were taken for granted; they constituted the independently given variable. To obtain a dependently variable measure of auditory perceptibility Wolf conducted the experiment he describes on page 59 of his book (Wolf, 1871: 59). He asked a trained professional speaker and two professional musicians to take part in the test. The professional speaker took up his position at the end of a long avenue of trees, in calm conditions, and was instructed to produce each of the test stimuli with equal effort. One of the two musicians stood beside him and was instructed to monitor the realized effort of the stimulus production. The other musician served as test subject. He had to take steps forward and backward along the avenue in order to determine the step distance where the test items could still be clearly identified. The resulting step distances can be seen in Figure 4 in the (reprinted) original form.

Wolf's experiment had a very strong influence on the further theoretical development of phonetics as an experimental discipline. Despite certain methodological deficiencies, it showed that in principle it was

possible to characterize the speech sounds under examination by means of independent measures.

Eduard Sievers (1876), and later Otto Jespersen (1904), used the sonority scale invented and experimentally determined by Oskar Wolf to formulate their phonetic syllable theories. They assumed that the syllabic prosody of speech could be understood as a function of the degrees of sonority in pronounced sound sequences, with the vowels forming the sonority peak in the center of the syllable and the marginal consonants creating troughs of sonority between the peaks.

Segmental States and Fast Intersegmental Transitions

Phonetics as established during the second half of the 19th century, as a branch of linguistics, had two main orientations: a theoretical one and a more practical one. The success of the latter mainly consisted in the practical application of the new articulatory categories to produce reliable phonetic transcriptions. The French phonetician Paul Passy (*see* **Passy, Paul Edouard (1859–1940)**) was one of the initiators of the famous Association Phonétique Internationale (API)/International Phonetic Association (IPA)/Weltlautschriftverein (WLV), founded in 1886 (*see* **Phonetic Transcription: History**). One year later, in Marburg, Wilhelm Viëtor (*see* **Viëtor, Wilhelm (1850–1918)**) started the first important, international journal of the new discipline, entitled *Phonetische Studien. Zeitschrift für wissenschaftliche und praktische Phonetik mit besonderer Rücksicht auf den Unterricht in der Aussprache*. Both orientations are specified in the subtitle of the journal, and the practical aspect of teaching pronunciation is also particularly mentioned. The number of the cooperating persons whose names were printed on the cover increased within 2 years from over 50 to nearly 90. This 'editorial board' contained the names of practically all the leading phoneticians of the time including Bell, Brücke, Ellis, Jespersen, Lloyd, Lundell, Noreen, Passy, Storm, Sweet, Techmer, and Winteler.

The theoretically oriented scientific branch of phonetics developed in close relation with the continuing rise of the natural sciences, but was at the same time strongly influenced by new programmatic concepts of linguistic theories. The more the new phonetic knowledge became available to linguists, the greater was its role in helping them to comprehend and explain the processes of sound change in the evolution and branching of documented historical languages. With the neogrammarian school of comparative philology (*see*), the new insights provided by sound physiology and the articulatory description of speech sounds became an integral part of linguistics, and phonetics gained basic concepts from the theories of historical linguistics for its further scientific development.

Eduard Sievers (1850–1932) can be regarded as the phonetician of the neogrammarian school of comparative historical linguistics. His book on the principles of sound physiology was written as an introduction to the study of the sound theory (*Lautlehre*) of the Indogermanic languages. First published in 1876 (in later editions the term *Lautphysiologie* in the title of the book was replaced by *Phonetik*), it had a strong influence in two directions: first on the further development of theoretical linguistics, and second, regarding a new theoretical foundation for phonetics as a linguistic discipline. At the same time, Sievers, like Techmer (see below), anticipated the creation of instrumental and experimental phonetics in a programmatic way.

Analysis Versus Synthesis An important new issue in the development of speech science was the theoretical distinction between speech analysis and speech synthesis. Alphabetically representable speech sounds were no longer understood as directly observable, but rather as the elementary results of an abstracting analysis. As soon as these elementary units of speech description were used for the representation of real speech, it became clear that additional phonetic properties of speech had to be specified. One of the questions typically asked in this connection was, for instance, how the uniform elementary units of a sound alphabet could be used to generate such differently sounding utterances as those of English, French, or German. (One of the answers given to this interesting question consisted in simply assuming a different language-specific general setting of the articulatory organs, the so-called basis of articulation, *Artikulationsbasis*.)

Speech synthesis not only meant putting together alphabetic units into real syllables, words, and sentences, but also the description of the different prosodic and rhythmic organization of speech utterances. In particular, the assumed fast transitions between the assumed steady sound segments were thought to play an important role in historical sound changes. In this respect, assimilations and dissimilations in the phonetic formation of individual words gained special interest, of course.

Sievers – and later Jespersen – understood the distinction between analysis and synthesis not only as a fruitful heuristic program, but also as absolutely necessary for understanding and describing the physical reality of speech. In 1884, Friedrich Techmer (1843–1891) attempted to formulate a complete theory of phonetic speech communication. His 'scientific analysis and synthesis of audible language' is still very modern ('scientific' is meant in the sense of natural sciences:

Naturwissenschaftliche Analyse und Synthese der hörbaren Sprache). Techmer distinguishes seven stages involved in the "cycle of audible language" on its "way from inside to outside" and "on the way from outside to inside." He gives a detailed description of these stages taking into account all knowledge available to him at that time. At the respective stages 1/7, 2/6, 3/5, he describes the psychic, psychophysical, and physiological activities within the communicating organisms and at stage 4 the physical processes outside of them. A central role in the generative process of speech synthesis is played by the syllable. Accordingly, speech sounds are characterized by means of a threefold dichotomy. Each speech sound is physiologically either *Mundöffner* (mouth opener) or *Mundschließer* (mouth closer), physically either *Klang* (complex tone) or noise, and perceptually either *Phon* or *Symphon*. All vowels are 'mouth openers,' *Klang*, and *Phon*. Techmer's important work served as a model 20 years later when Scripture wrote his standard work on experimental phonetics, which also contained a complete theory of speech communication.

Theoretical Assumptions Leading to Early Instrumental Phonetics When Sievers (1893), in the preface to the fourth edition of the *Grundzüge*, showed himself not to be too enthusiastic about the "new experimental phonetics of recent years" he did not seem to realize that the turn in this direction was also a consequence of certain basic theoretical assumptions about speech science that he and his linguistic colleagues had introduced and advocated in their publications in the years before, especially in connection with the explanation of sound change.

First the typical view of speech perception as subjective as opposed to speech production as objective will be mentioned. According to this – almost behaviorist – view, a listener was often considered as only 'believing that he heard something,' – something that in reality was not objectively present. Sievers observed that naive listeners, in particular, were normally systematically misled into hearing the sounds of their own dialects, and he therefore very insistently argued that linguists should train their ears as much as possible in order to learn to hear the relevant articulations. Techmer points out that thanks to the new instruments "we now are able . . . to control the ear through the eye." Speech perception was not an interesting problem in its own right, its only task was to transport the speech sounds "on their way from outside to inside."

The second assumption is the most important in the context of this article. It is concerned with the concept of infinitely fine sound varieties in the transitions between steady state sound segments. Sievers (1876) argued that given a sound sequence such as [la] or [al] it is

> intuitively obvious that during this transitional movement neither the pure a-sound nor the pure l-sound can exist, but that rather between the pure a produced at the beginning and the 1 at the end a continuous series of transitional sounds must be interposed (Sievers, 1876: 85).

Because these transitional sounds (*übergangslaute*) were assumed to be much too short for them to be heard, the only conclusion to be drawn was that one should use instruments for getting a description of all the postulated relevant variants.

A third very general – and, from the point of view of today's theory of science, also very naive – assumption was that there exists just one, objectively given, reality of speech acts, a 'real reality' in the physical world, which at the same time constitutes the contents of subjective (and imperfect) perception and of objective scientific description. A peculiar consequence of describing a physically given world with normal words was that the continuous and transitory process of speech articulation was automatically segmented according to previously given categories, such as places of articulation at which an articulatory organ produces just one of the given possible manners of articulation. When this epistemological paradox became clear to Otto Jespersen he invented a new system of phonetic description (1889) that worked without 'semantically segmenting' categories such as manners and single places of articulation (for this analphabetic notation **Phonetic Transcription: History**). In an analphabetic representation of speech, the whole configuration of the articulatory speech production system from the lungs to the lips is given, either as fixed within a time segment or as a transition from one configuration to another.

It was precisely the naive identification of two realities, one of them being measurable by means of instruments in the physical world, and the other being what linguists described phonetically as observable speech sounds, that provoked the emergence of instrumental phonetics. Some 30 years after Jespersen's use of the analphabetic notation to represent the articulatory synthesis of speech, one of the leading Dutch speech scientists, Zwaardemaker (1927), tried to realize a complex kymographic system for graphically producing a directly measurable analog of this analphabetic notation.

Early Instrumental and Experimental Work

After the very successful eras of sound physiology and articulatory phonetics, a new generation of speech

scientists showed a growing distrust of the methods of direct observation and direct transcription. Shortly before the last decade of the 19th century, they had begun to use new types of instruments to measure speech data. In most cases, they recorded time functions representing either the movement of certain articulatory organs, or the acoustic speech output, resulting in an oscillogram of the speech wave in a somewhat restricted and not yet analyzed form.

The method of direct observation was replaced by the method of indirect measurement. At the beginning of the 20th century, the mainstream of speech science had definitely left the domain of comparative philology and linguistics and was moving into the domain of the natural sciences. Within a short period of time, several new laboratories for experimental phonetics were established at different universities in Europe and the United States. The new approach of experimental phonetics was to study speech sounds exclusively in the form of the graphically presented speech curves that could be produced by equipment specially developed for the purposes of instrumental phonetics. The possibility of transforming transient speech into the graphic curves of measured speech data that remained stable for closer inspection introduced a new kind of experimental work into the mainstream of speech science, work that in principle was based on arbitrarily reproducible observations made under controlled repeatable conditions with systematic variation.

Measurable Speech Movements and Readable Speech Curves

Ten years after Marey had published his *Méthode graphique dans les sciences expérimentales* (1878) in Paris and Leipzig, two young linguists, independently of each other, were the first to try to make use of the proposed method in speech science: they used it to transform transient speech utterances into persisting graphic registrations, and they were both interested in getting as precise a description as possible of a particular dialect; Wagner (1891) of a dialect in South Germany, Rousselot (1891a) of his own Gallo–Roman dialect (*see* **Rousselot, Pierre Jean, Abbé (1846–1924)**). Wagner tried to measure certain sound durations in order to determine the quantity relations in the sound system of his dialect. E. A. Meyer (1898) reanalyzed his data and also improved the instruments used by Wagner in order to get more reliable measurements.

In the first chapter of his dissertation, Rousselot produced a great variety of graphic speech curves for detailed inspection and description. He certainly believed that speech utterances could be reliably and authentically replaced by these rather poor graphic registrations and he obviously liked the art of reading these curves, *la lecture des tracés*; a great part of his later work consisted simply in presenting, and using his skill in 'reading,' speech curves. One may say that he invented a new kind of 'speech curve philology.' Thus his publications were full of phonetically interesting individual observations. Scripture (1902), in his broad, systematic attempt to present the new discipline of experimental phonetics as a central part of experimental psychology in the tradition of Wilhelm Wundt (*see* **Wundt, Wilhelm (1832–1920)**), quotes no less than 30 of these observations.

There is yet another reason why Abbé Rousselot was so successful in directing the main stream of speech science into experimental phonetics. The interest in reading speech curves constituted a new scientific program. The aim of Rousselot was not to find the invariant common features of a given sound in different realizations, but on the contrary to discover differences in the realizations of a given sound in the pronunciation of a given word. Most of his material consisted of lists of words or short word sequences. This new program was already clearly expressed in 1891 in the title of his dissertation, *Les modifications phonétiques du language* (1891a), and in another contribution from the same year, entitled *La méthode graphique appliquée à la recherche des transformations inconscientes du langage* (1891b), Rousselot presented his arguments for this new kind of speech curve philology. All sound changes in the histories of all languages, he maintained, are caused by phonetic modifications unintentionally produced by the speakers, and the resulting 'subliminal transformations' in the phonetic form of the utterances can only be studied after they have been made visible in the registrations produced by the new graphic method.

The Kymograph The registrations of speech curves were produced by an instrument called the kymograph. In the development of instrumental phonetics it played a role similar in its importance to that played 50 years later by the sonagraph. It could be used for the registering of rather slow air pressure variations up to about 500 Hz. It consisted of a drum that was covered with smoked paper and was kept in constant revolution by means of clockwork during registration. So-called Marey tambours, flat circular metallic boxes with a rubber top and a side tube, were used to receive and transduce the air pressure variations. A light lever, usually of straw, was fixed to the rubber membrane at the top of the tambour to follow its movements, which were simultaneously inscribed onto the revolving smoked paper by means of a light quill at the end of the lever. The membrane of the tambour reacted to the air pressure either directly or indirectly. The first case is shown in Figure 5 where

Figure 5 Kymographic recording of mouth airstream and glottal vibration (from Panconcelli-Calzia 1924: 14, © De Gruyter, Berlin. Reproduced with permission).

the speaker presses a funnel around his mouth in such a way that the resulting air stream from the mouth is conducted directly through a rubber tube into the tambour. In the picture shown, the glottal vibrations are indirectly transmitted to a second tambour.

For recordings of the movements of the lips or the jaw, direct and indirect methods could be used. In the latter case, levers fixed to the articulatory organs had first to transmit their upward and downward movements to the membrane of a receiver tambour. The resulting air pressure variation was then transmitted through a rubber tube into a second recording tambour at the site of the kymograph. The indirect method could also easily be used for the registration of the vibrations of the larynx during the production of voiced speech sounds. In this case, the membrane of the receiver tambour could be applied directly to the neck, as shown in Figure 5.

Whereas Rousselot and most of his colleagues and followers were quite confident of the reliability of the resulting kymograms as measurements of the articulatory speech processes under investigation, Meyer (1898–1899) rigorously analyzed the problematic time constants of the system and showed how limited the use of the kymograph actually was for a precise measurement of the underlying time functions. He took the limitations of the kymographic system into serious consideration when he used it for determining the perceptual centerpoint of syllables in rhythmic speech production by simultaneously recording kymograms of the mouth airstream and of hand tapping. Meyer argued that in reality the production of words and sentences involves movements of the articulatory speech system far more complex and complicated than can be seen even from a large set of simultaneously taken kymographic recordings.

Simultaneous and Successive Speech Movements It is impossible to sum up all the individual observations and speech measurements that were made by use of the kymograph during the first 40 years of the 20th century. One could easily fill a database with the published results, even though in many cases it would then be less easy to classify these results according to the concepts and categories of today's speech science, which were not available to the early instrumental phoneticians. In other cases, the results of kymographic investigations have led directly to, or have at least strongly influenced, the development of certain modern concepts. Details of measurements of the specific velocity of different articulatory organs such as the upper and lower lip, the tip and the body of the tongue, the velum, and many other very interesting data, collected by Louise Kaiser from a large population of Dutch students may be found in Kaiser (1934, 1943).

There is one more general aspect of kymographic work that needs to be mentioned and exemplified. Typically more than one time function was recorded at the same time. Rousselot argued that only the comparative inspection of several simultaneously taken speech curves could help to reveal what he called a 'registration error' (*erreur d'inscription*). For him and his closer colleagues, the speech curves had to be interpreted in relation to the underlying articulatory processes, and only if this interpretation led to a clear picture would the kymograms be regarded as usable. This was especially true when the curve reader had to draw segment boundaries between the individual speech sounds. In this case, only the comparative inspection of several simultaneously recorded curves was accepted as giving the relevant hints. If a segment boundary could not be determined unambiguously the kymograph was said to have failed, and the faulty kymogram was replaced by a new and better one. This highly questionable methodology had to be adopted by all those who wanted to measure sound or syllable durations and the like. Those who decided for methodological reasons that the instrument used could not make mistakes had to draw the conclusion that the phonetic form of speech is itself nothing other than a continuous movement.

Different Voice Onset and Voice Offset Times Comparing a French and a German speaker articulating simple CV-sequences such as [ba] and [pa], with a voiced or voiceless stop followed by a vowel, Rousselot (1897–1908: 454–456) discovered that they showed a typically different voicing behavior in the production of the stops. He compared kymograms containing the airstream curve of the mouth and the vibration curve of the larynx. With modern knowledge about the distinctive function of the onset of laryngeal phonation relative to the point of stop release in the mouth, Rousselot can be said to have

discovered that the French speaker produced the voiced stop with negative voice onset time (VOT) and the voiceless one with zero VOT, whereas the German had zero VOT in the case of the voiced stop and a clear positive VOT in the case of the voiceless stop. But it must also be recognized that Rousselot did not look at these differences from a functional point of view. His conclusion was that such theoretical distinctions as the one between voiced and voiceless stop consonants can be realized by quite different phonetic forms in different languages or dialects. That the phonemic principle (**Phoneme**), according to which a distinctive opposition is created between minimal pairs of words, did not play any role for Rousselot can be inferred from the fact that he discovered and described different voice onset and offset times in those situations also where they did not have any contrastive function. His final conclusion was that in addition to the voiced and voiceless consonants, intermediate sound variants must be introduced. In French he called them *demi-sourdes* and *demi-sonores*.

That the linguistic function of the observed voice onset and offset times was not really a central issue for the early instrumental phoneticians can also be inferred from Panconcelli-Calzia (1919). He argued that the use of words such as 'semivoiced' or 'semivoiceless' is too vague to describe all the possibly occurring situations in a precise way. He proposed to characterize both the degree and the place of voicing by means of two measures, *pi* and *tau*. The measurement of the voicing degree, *pi*, was also explicitly called *Phonoposotometrie*, whereas *tau* was the value of the so-called *Phonotopometrie* chosen to determine the local stretch of voicing within a given segment. To get normalized values, the length of any given segment under consideration was divided into 10 equal parts. Thus the normalized degree *pi* of voicing could vary in steps from 0 to 10. The *tau* value then, of course, is of interest only if the *pi* value differs from 0 or 10; $pi = 0$ indicates no voicing at all and $pi = 10$ indicates voicing throughout the whole segment. The topometric *tau* value determined the beginning and length of the voicing stretch, again in steps of 10% of the segment duration. In Figure 6 (reproduced from Panconcelli-Calzia, 1924), a dozen pairs of speech curves illustrating different voicing situations can be seen. The upper curve of these pairs always shows the airstream time function from mouth or nose, the lower one is always the larynx curve showing or not showing glottal vibrations. Only curves #1 and #11 demonstrate a completely voiceless and a fully voiced sound segment. Examples #3, #7, and #12 are voiced only in the initial part of the segment, examples #2, #5, and #9 show voicing only in their final part, curves #4, and #10 depict segments with a devoiced central part of the segment, whereas curve pair #8 has voicing vibrations only within its central part.

Panconcelli-Calzia knew that from a linguistic point of view the importance of his absolute *pi* and *tau* measurements was only of a

> relative nature. Because in a language where certain sounds show voicing with a degree of pi = 10, sounds having pi = 5 [...] must be considered as voiceless, while in another language, where pi in optimal cases is equal to 5, all sounds with pi-values of 4 or 3.5 must be considered as voiced (Panconcelli-Calzia, 1924: 45)

This quotation shows that the linguistic function of VOT, while not playing a central role, was not totally neglected.

Measured Durations of Sounds, Syllables, and Words

As soon as segment boundaries were drawn across the speech curves of a kymogram, the duration of the resulting sound segments could be very easily determined. In fact, this type of quantitative speech data gave rise to a large number of investigations which produced many interesting results. Only a few of them can be briefly mentioned here.

The first surprising fact that could be directly observed in the measured data itself was the great amount of variation in segmented durations. Variation as such was of interest for the reasons already mentioned, especially for those concerning the possibility of explaining sound change. But there was also the question of whether one could discover the systematic factors behind the observed variation.

Rousselot (1891a) was the first to try to answer this question in an experimental way. He chose nonsense words as test items and systematically varied their phonetic structure. In VCVCV test items with the vowel [a] in the V-position and one of the consonants [p, f, t, s, k, ʃ] in the C-position, he found that the stops were slightly shorter than the fricatives. In VCV items with the nasalized vowel [õ] and one voiced or voiceless consonant such as [v, f, d, t] in the intervocalic position, the voiced consonants were a little shorter than the voiceless ones. In CVC, CVCVC, and CVCVCVC sequences, the duration of the sound segments decreased as a function of the number of syllables. Rousselot could also show that a stressed syllable had longer segments than the same syllable without stress. And he also discovered that the last consonant in a word uttered in isolation is generally lengthened. This corresponds to the well-known fact that the duration of sound segments is normally increased at the end of an utterance, a fact that has been described in more detail by Binet *et al.*

Figure 6 Phonoposoto- and phonotopometries (from Panconcelli-Calzia 1924: 42, © De Gruyter, Berlin. Reproduced with permission).

(1894). Many of Rousselot's early observations have been confirmed and partly refined by later investigators.

Grégoire's investigation *Variations de durée de la syllable française*, published in 1899, was the pioneering work for all following kymographic studies of duration. In his kymograms, he recorded both the airstream from the mouth and glottal vibrations from the larynx. His test items consisted of sequences of real French words such as *pâte:pâteuse:pâte* or *pâteuse:pâte:pâteuse* where the voiceless stop consonants facilitated the segmentation of the speech curves. Grégoire pointed to the fact that the intervocalic stops caused a silent interval between the vowels that was often nearly as long as the preceding vowel, and it should be mentioned that he tried to explain why this silent pause within the word is not actually noticed as an interruption of the word. Instead of formulating the rule, well known in modern speech science, that short silent intervals of this sort are perceived as stop consonants, he argued that the motor activity of the speech organs goes on just as vigorously during the silent occlusion as before and after it, and thus unifies the auditory parts in the hearer by way of association. In addition, Grégoire again observed the lengthening of the final syllable of a word before a pause. In accordance with the CVC, CVCVC, and CVCVCVC observations of Rousselot mentioned above, Grégoire also discovered that the long syllable of a monosyllabic word becomes shorter and shorter when further syllables are added, as could be shown in the kymograms of the French words *pont, pontife, pontificat*, and *pontificalement*.

Grégoire's findings stimulated many other investigations concerning the law-governed variation of the duration of kymographic segments of sounds, syllables, and words. In particular, languages having phonological quantity contrasts attracted many investigators. Figure 7 gives an example from Panconcelli-Calzia (1924: 115) who used this kymogram of mouth airstream curves to demonstrate the quantity differences in the Italian minimal word pair *topo/toppo*. The time reference at the bottom of Figure 7 is a 100 Hz oscillation. The closure duration of the geminate p-stop in *toppo* is nearly 380 ms and is more than twice as long as the short stop in the contrasting word. But in the word *topo* the duration of the preceding vowel is much longer than in *toppo* as can be easily seen in the upper mouth airstream curve of Figure 7.

E. A. Meyer devoted several extensive and carefully conducted studies to the duration of vowels and consonants in English (1903), German (1904), and Hungarian (1909). Besides many language-specific regularities that he was able to describe, he also discovered the so-called general law of vowel quantity,

Figure 7 Kymograms of the mouth airstream curves of the Italian minimal pair *topo/toppo* (from Panconcelli-Calzia 1924: 115, © De Gruyter, Berlin. Reproduced with permission).

which states that the duration of a vowel is correlated with its tongue height. This *Eigendauer* of vowels (intrinsic vowel duration, increasing from [i] and [u] to [a]), cannot be explained – as Jespersen had tried to propose – by the longer distance the tongue has to travel from the consonantal place of articulation to the vowel target. As Meyer could show, the characteristic intrinsic values of vowel duration do not disappear if the vowel is embedded between labial consonants. The same is true for vowels in word final position.

In another famous investigation, Menzerath and de Oleza (1928) drew and measured more than 7800 sound segments in the kymographic recording of Spanish words read in citation form. The word material was organized first of all according to the number of syllables, words of 'Typ I' having one, of 'Typ VII' having seven syllables. The second criterion was the position of the stressed syllable, counted from left to right: thus a word of 'Sub-Typ V 3' consisted of five syllables and had lexical stress on its third syllable. The third criterion was the number of sounds in the word of a given subtype. The analysis of the detailed results, presented in 29 tables and 11 diagrams, led to the formulation of no less than 12 general and 50 specific laws of quantity. The systematic behavior of syllable durations can be seen from one of the original figures reproduced in Figure 8. Here the mean duration of the syllables of the subtypes is represented by the diameter of a small circle, the circle of the stressed syllable being given a special mark. Stressed syllables always have a longer duration. Prepausal lengthening is clearly present in all 23 polysyllabic subtypes of words. The marked circles in the first column show the mean durations of all syllables in the given type of word. The duration of the syllables of a word decreases with the increase of the type number, as can be seen from Figure 9 where the mean syllable duration of a word is presented as a function of Types I to VII.

In 1931, Weitkus published a similar extensive investigation based on the kymographic measurement of the duration of sounds and syllables in German sentences. He also considered the effects of different speaking rates. His final results are given in a concentrated list of 70 individual items. His work can be understood as a first step in the direction of the new 'phonometry' proposed by the Zwirners (see 'Acoustic Nature of Speech Sounds' below).

The First Crisis in Experimental Speech Research: Segmentation Problems and the Discovery of Coarticulation

Not all speech researchers analyzing kymograms were convinced that the given speech curves could be unambiguously segmented into single alphabetic units, according to the prevailing theoretical assumption that the utterances of speech acts consist of stable and steady segmental states and short and fast intersegmental transitions. A few critical researchers had decided to believe only in what a kymogram really showed itself, and ignored the interpretations of the skilled reader. Scripture (1902), for instance, was clearly convinced that the most important result of experimental phonetics was the discovery that phonetic utterances had the form of the measured speech curves – thus for him all vowels were in reality 'more or less' of the nature of diphthongs, and alphabetically represented speech sounds existed only as a product of perception.

Another prominent researcher, Panconcelli-Calzia, argued that sound segments or syllables had no phonetic reality at all. He called such units a pure fiction, an invention of linguists. He tried to prove this (Panconcelli-Calzia 1924: 23) by showing a pair of speech curves taken from the chest of a subject uttering the German word *Lokomotive*, first of all in a scanned version putting heavy stress on each individual syllable, and then in normal pronunciation: "the syllable is only there if it is intentionally produced, i.e., by means of extra chest pulses (see Figure 10).

When in 1930, Gutzmann, at a meeting of the International Society of Experimental Phonetics in

Bonn, showed the first cineradiographic film of running speech, the audience was shocked, as Scripture reports:

> The impression of such a film is overwhelming. The organs of speech do not remain still for an instant, every speech act is the combination of the movements of all organs of the mouth, the throat, the larynx etc., and this combination is deployed over time. Sound positions simply do not exist. One understands at once that the sound physiology up to now has been based on an illusion and one awaits new explanations (Scripture 1932: 173)

Here the crisis of modern speech research – the impossibility of mechanically identifying the sound units of an alphabetic speech transcription – became evident for the first time. The paradoxical situation was that instruments had been introduced to replace subjective hearing by objective measurements, but the resulting picture did not show what was originally looked for: visible speech sounds. These had disappeared and had to be reinvented by the new phonologists (*see* **Prague School**).

A phonetic way out of the dilemma was proposed in 1933 by Menzerath and de Lacerda in their study *Koartikulation, Steuerung und Lautabgrenzung*. They used the kymographic method to show that speech sounds at the beginning of a syllable are coarticulated, i.e., produced at the same time, and that the vowel in a syllable rhyme is stopped ('controlled') by the following consonant if there is one. Menzerath and de Lacerda observed various coarticulatory phenomena; however, in modern terms, *Koartikulation* for them mainly seems to refer to the anticipation of consonantal and vocalic features in syllable initial position, whereas carry-over effects cannot easily be related to their concept of *Steuerung*. They formulated the theory that the complex combination of all simultaneous movements of the speech organs, which they called 'Synkinese,' existed only for the purpose of producing 'acoustically' a sequence of clearly sepa-

rated and directly segmentable sound units. But in their new theory, they failed to make any distinctions between purely acoustic sound segments in the physical world and the auditorily perceived sounds, which again were taken as a common reality, an assumption that would later lead to a repetition of the first crisis.

Acoustic Nature of Speech Sounds

Before the mainstream of speech science, after the invention of a new kind of visible speech in the 1940s (*see* **Speech Synthesis**), moved on to an extensive acoustic analysis of speech as well as to the early experiments concerning auditory speech perception (*see* **Speech Perception**), there already existed a solid foundation of phonetic knowledge about the acoustic nature of speech sounds.

Brücke (1856) already had a good knowledge of the intrinsic pitch of vowels, and he clearly distinguished between the respective contributions of the vocal tract and the larynx to the acoustic formation of speech sounds. He repeated some of Willis's experiments (*see*) to demonstrate the separate effects of glottal phonation and the resonances in the vocal tract. Thus he could explain the audible effects when a female singer produces an [u]-vowel with a very high pitch. He also observed, by touching the Adam's apple with the tips of his fingers, that the length of the vocal tract varies with the tongue height of vowels.

The first person to look at specific pitch movements within the vowels of spoken and sung single words on the basis of measured fundamental frequency (F_o) values was Meyer (1897). He also described F_o-perturbations caused by the consonantal environment. Many detailed descriptions of variations in the F_o-contours can be found in the periodical *Vox* edited by Panconcelli-Calzia, especially in the years between 1911 and 1930. These include the influence of a prevocalic breathy onset or of a glottal stop onset on the measured F_o-frequency; the syllabic F_o-contours of the tones of West African tone languages; the international F_o-contours of questions, commands, exclamations, requests, or neutral statements.

In his *Lehre von den Tonempfindungen*, first published in 1863, Helmholtz had introduced Fourier's harmonic analysis to explain vowel sounds in terms of complex tones. In 1861, Scott had invented the 'phonautograph' to register the vibration of a membrane in the form of an oscillogram. He referred to this as a direct way for the 'writing of sounds.' Paul Wendeler (1887) was one of the first to publish a comprehensive selection of speech oscillograms in his *Versuch, die Schallbewegung einiger Consonanten und anderer Geräusche mit dem Hensen'schen Sprachzeichner graphisch darzustellen*. Pipping (1890) improved Hensen's recording method, and presented the first manual computation of complete phase and amplitude spectra of sung vowels. In 1894, Hermann discovered the nonharmonic formant frequency that led to the long dispute between the Helmholtz/Stumpf and the Hermann/Scripture supporters, a conflict that was totally superfluous and unnecessary, as became known later. In the Z-transform X(z) of a digital speech signal x(n), the nonharmonic formant frequencies correspond to poles within the unit circle of the plane of the complex variable z, whereas harmonic components result, if the Z-transform is evaluated at integer multiples of the respective roots of unity directly on the unit circle itself. Stumpf published the results of his 'experimental phonetic investigations' in a book of more than 400 pages (Stumpf, 1926). Most other pioneers of acoustic phonetics had analyzed recordings of a speaker who was asked to produce a certain speech sound. Stumpf conducted perception experiments and introduced his own 'analysis by synthesis' method to determine the acoustic properties of voiced and whispered vowels and consonants.

The relation between acoustic and articulatory speech data was discussed and analyzed very early by Lloyd (1890–1899) in a series of articles entitled *Speech Sounds*: *Their Nature and Causation*. He criticized the fact that phoneticians either "investigate speech on the side of sound" or "on that of articulation" and argued "that each is necessary to the other's completeness" (Lloyd, 1890: 251). One of his aims was to explain "why certain dissimilar articulations are found to produce very similar sounds, or why, conversely, certain small changes in articulation have a great effect upon the quality of sound" (Lloyd, 1890: 252). Lloyd's questions are still of great interest.

On the basis of a statistical analysis of acoustically segmented and linguistically labeled speech data, the method of phonometry was proposed by E. and K. Zwirner (1936), as another way out of the lost speech sound dilemma described above. They believed in the binomial distribution of the acoustic properties of sound segments, and assumed that the mean value of acoustically segmented and auditorily labeled parameters could represent the relevant norm historically given in a speech community (according to the theory of Hermann Paul concerning use and norms.)

Conclusion

The historical fact that the early inspection of speech sounds through direct perception, whether visual or aural or even tactile, was replaced by the inspection of

graphically given speech curves led to a paradoxical situation. On the one hand, it is true that more and more new properties of speech sounds were discovered, but on the other hand the linguist has to admit that certain fundamental theoretical concepts concerning the general nature of speech sounds, as well as the possibility of developing a systematic theory of speech sounds, had finally been lost. The ensuing bifurcation of the mainstream of classical speech science into instrumental and experimental phonetics on the natural science side, and phonology and theories of sound systems of individual languages on the linguistic side, as well as the eventual reunification of the two separated streams into the speech science of the late 20th century is outside the scope of this article.

Introduction

Sociolinguists are continually grappling with the trade-off between conducting research under good scientific conditions and conducting research that examines the way people naturally talk – the focus of our field. Therefore, our research practices consist of various combinations of efforts to record naturally occurring speech and efforts to control the context of speech production as much as possible. **Figure 1** lists different types of data collection methods that are frequently used by sociolinguists: (1) from easiest to collect and analyze to hardest to collect and analyze, and (2) from least representative of natural speech to most representative of natural speech.

This chapter focuses on the experimental methods, or controlled conditions, aspects of our research methodology (those items toward the bottom of **Figure 1**), leaving aside the discussion of 'naturalistic speech,' as collected via the main portion of the traditional sociolinguistic interview. The traditional battery of field experimental techniques implemented by Labov (subjective reaction test, minimal pair test, commutation task, self-report, and the linguistic security test) are well described in Labov (1984). I therefore focus on more recent innovations.

To motivate the need for more experimental techniques, even though they diverge farther from naturalistic speech, I begin with one example to illustrate that even a method like eliciting a translation may not provide sufficiently controlled speech samples. I was eliciting imperative and interrogative forms from a speaker of Faitare by providing phrases in Italian that he was to translate. After several successful iterations, we had the following exchange:

1. NN: Diamo il libro al ragazzo.
   Let's give the book to the boy.
2. M81: Denà lu lìvere a lu quattrà.
   Give the book to the boy.
3. NN: Hai datto il libro alla mama?
   Did you give the book to the mother?
4. M81: Gloje. *Yes.*

Lines 1 and 2 show a successful translation of an imperative. However, lines 3 and 4 show a failure at the translation of an interrogative. In this case, it was immediately apparent that line 4 was not a translation of line 3, but such transparency doesn't always exist when a fieldworker works in an unfamiliar speech variety (Nagy, 2000). The more the linguistic content can be controlled, the more the linguist knows what she is analyzing, but the less she is analyzing naturalistic speech. A variety of methods must be used because each has its shortcomings.

This principle has been applied since the earliest American sociolinguistic studies. Labov's (1963) study of Martha's Vineyard consisted of speakers reading brief passages, word lists, and minimal pair lists in order to efficiently elicit the same sounds in the same (phonological and stylistic) contexts from a variety of speakers, in addition to recorded conversations. In his New York City studies (Labov, 1966), the Rapid and Anonymous technique was added, in which efficiency and naturalistic speech production were combined. The fieldworker asked each subject one question designed to elicit the same phrase (the now widely cited 'fourth floor') and then asked for one repetition, as if he hadn't heard. All the subjects (department store employees) had to do was answer. In this way, data on the production of /r/ was collected from a large number of speakers from different demographic categories. In all likelihood, these speakers did not know they were participating in a linguistic experiment.

In recent years, there have been three main developments, all of which had their roots in Labov's earliest work. The first is the rise of improved recording techniques allowing for the combination of acoustic analysis and variability studies (giving rise to a field called 'sociophonetics'). The second is perception studies that examine how listeners evaluate certain speech patterns. The third is an increase in the number of studies that combine real-time and apparent-time techniques.

Figure 1 Continuum of sociolinguistic research techniques.

Recording Issues

Because sociophonetic analysis depends on high-quality recordings of speech, I first mention some relevant technological developments. The type of microphone, recorder, recording medium, hardware, and software used makes a big difference in the measurements achieved. A series of presentations by Plichta and his colleagues (cf. Plichta and Mendoza-Denton, 2001; Plichta Website) have been useful in bringing the field up to date on some important mechanical issues. For example, Plichta (2004: 38, Fig. 16) clearly shows the effect of the choice of microphone on how vowel formants are analyzed. Plichta (2004: Chapter 2) explains the utility of aerodynamic measurements of oral and nasal airflow for greater accuracy of formant recognition and provides a dynamic and highly automated method for acoustic analysis.

Plichta (2004: 100) presents a method of presenting speech cues on a laptop computer, which allows for greater mobility. By making it possible to bring the lab to the speakers, rather than vice versa, we make a step in overcoming the Observer's Paradox – speakers are a little bit closer to their natural (unobserved) habitat. On the flip side, Plichta (2004: Chapter 2) makes a strong case for the use of fairly invasive microphones and nasometers to achieve more accurate acoustic measurements. This illustrates that experimental techniques may reside at either end of the continuum represented in **Figure 1** – naturalistic but complicated, or non-naturalistic but simple.

Perception Studies

Two types of perception studies exist. In one, listeners are asked to make judgments about what is said. In the other, they are asked to make judgments about the speaker(s). An example of the first type is Labov and Ash (1997, cited in Fridland and Bartlett, 2004: 5), which examined how well listeners identified Southern vowels. An example of the second type is Wolfram *et al.* (1999, cited in Fridland and Bartlett, 2004: 4), which examined how various productions of open-o words influenced judges' (the research subjects, or listeners) ratings of the Northerness or Southerness of the speaker.

However, these two types are not as distinct as one might first imagine. Their interconnection is illustrated in the following studies. Niedzielski (1999) conducted a clever perception study in which judges from Michigan, all of whom heard the same voices, were led to believe that they were listening to either Canadian or Michigander voices. She illustrated that who they thought they were hearing significantly influenced how they heard certain vowels (as raised or nonraised variants of /aw/). Similarly, Strand (1999, cited in Plichta and Preston (2005: 25) shows that judges' expectations of typical male versus female identity affect their perceptions of sibilant consonants. Atagi (2004) shows the extreme effects that can occur in studies where judges are asked to make linguistic judgments but are clearly influenced by their social judgments. Judges all listened to the same speaker, but the speaker was labeled as either a native speaker of English or a non-native speaker, and labeled with an ethnicity differing to various degrees from that of the judges. These labels strongly influenced the judgments of fluency and nativeness made by the research subjects (university students who thought they were judging the comprehensibility of native and non-native teaching assistants). In a further step, Atagi showed that, in a post-test, the judges were able to recall more content presented by the voices labeled as native speakers.

Studies of the perception of speech are not new; some early perception work by Lambert and colleagues (e.g., Lambert *et al.*, 1975: 129) provided information about how speakers of particular Canadian varieties were perceived. Lambert *et al.* introduced an experimental technique known as the 'matched guise test' in which bilingual speakers were recorded speaking each of their languages. Judges listened to a series of voice recordings without knowing that pairs of passages in different languages were produced by the same speaker. The judges were asked to rate the speakers on a variety of personality and demographic characteristics. The speech variety used had a strong effect on how the speaker was judged.

While utilizing natural speech and having judges engage in typical behaviors (judging people by how they talk), these early matched guise techniques did not allow the researcher to determine which aspect of the speech variety the listener was reacting to, nor even if it was anything in the speech at all, as opposed to general notions about the community being represented by a certain speaker. More recent studies overcome this shortcoming by controlling many linguistic features in order to isolate what triggers the judges' responses.

In a study of perceptual awareness and social evaluation, Fridland and Bartlett (2004) carefully controlled the content to which the judges responded. They used acoustically manipulated speech samples, producing artificial guises of Northern and Southern form, in which everything but the formant values was held constant. Judges were asked to rate each speech sample for how Southern it sounded. The judges' accuracy was correlated to whether the manipulated

variant resembled that present in their own speech community or not, and they showed an ability to respond to slight differences in formant structure.

Another approach was used by Clopper and Pisoni (2004). They played speech samples from different regions for judges who were asked to identify the region of each speaker. Clopper and Pisoni then acoustically measured some of the variants (in the samples) that are typically associated with either the North or the South. Correlational statistics were produced, "suggesting that those variants are most responsible for triggering regional association" (Fridland and Bartlett, 2004: 5).

Fast (2002) conducted a set of production, perception, and evaluation studies with a group of Quebec French speakers. In Fast's version of the Subjective Reaction test, "the informant was asked to listen to and evaluate a series of stimulus sentences. [...] for each variable, one of the sentences was read with a 100% non-standard realization of the variable, and one with a 100% standard realization" (Fast, 2002: 33). All other variables were produced with the standard variant, and all sentences were read by a single speaker (Fast, 2002: 33–4). While the production and perception techniques (subjective reaction, matched guise) she used were not innovative, she gained greatly by interweaving her interpretations of the two together. Among other benefits, "this allows an evaluation of the subjects' linguistic insecurity, and the extent to which they are motivated by overt or covert norms about language" (Fast, 2002: 22).

Preston (1989) played speech samples from a selection of geographically distributed sites. Judges were asked to identify which site each sample was from. Building on this method to further study the perception of /ay/, but avoiding effects of extraneous speaker differences (e.g., voice quality), Plichta and Preston (2005) presented to judges a variety of synthesized versions of /ay/ ranging from fully diphthongal to fully monophthongal. The judges had to indicate on a map which location they thought the speaker was from; on the map, a narrow band containing nine different sites stretched from the north to the south of the U.S. These judges performed better than they themselves thought possible, indicating a level of subconscious awareness tapped by this method.

Plichta (2004: Chapter 3) made some important points about perception studies. He pointed out that the typical two-way forced choice methods of judgments, where all variables but one are held constant, make experimental conditions less like real-life language use than necessary. He proposed an alternative approach in which many combinations of different variants are presented to judges and then multivariate statistics are used to tease apart the effects (Plichta, 2004: 98–9). He has also presented advances in automated methods of data collection and analysis to make such an approach less unwieldy (Plichta, 2004: 102–3, Plichta Website).

Grammaticality Judgments

The notion of a 'grammatical utterance' is still commonly based upon the non-experimental basis of gathering data through introspection (the linguist's own judgments). Labov (1975), however, demonstrated that speakers' judgments of their own competence are unreliable. One step toward a more experimental approach is to ask others (rather than just ourselves) to say whether something is grammatical or not. A more nuanced approached is to ask whether they think they themselves might say it, or if 'someone' (either from their own group or another) might say such a thing. Moving away from such explicit questions, Karins and Nagy (1993) developed an experimental method to test the status of WH-traces in GB theory (whether or not such traces block contraction). This approach involves subjects' interpretation of a sentence that is ambiguous only if, in their grammar, WH-traces do not block contraction. This allows us to understand whether a certain sentence interpretation is grammatical for a certain speaker without asking directly.

Surveys

Milroy and Gordon (2003: Section 3.2) provided a thorough overview of survey methods: mail, Internet, and face to face.

Combining Real and Apparent Time Methods

I conclude with a recent trend in the field that falls between experimental and natural: the use of a combination of Apparent and Real Time studies. This method (first introduced by Bailey *et al.* (1991) and revisited in Bailey (2002)) allows for further testing of the Apparent Time Construct, which claims that by contrasting the speech patterns of speakers of different ages, we can get a good sense of how the community's language is changing over the course of time. This approach requires concomitant examination of other demographic factors (e.g., sex and socioeconomic status) in order to distinguish stable age-graded variation from ongoing changes. This is an experimental approach in that there are efforts to control for a number of variables by collecting data in the same community at different points in time.

Labov included in his 1963 study a comparison with earlier reports of Martha's Vineyard speech, and a comparison of speakers of different ages, but this technique has been much expanded in recent years. For example, both Pope and Josey returned to Martha's Vineyard to see what had happened with the language in the last 40 years (Pope, 2003; Josey, 2004). They each replicated Labov's methodology in order to see how the speech patterns had changed over time, attempting to control for all other factors.

In Montreal, recordings of French speakers made in 1971 (Sankoff and Sankoff, 1973), 1984 (Thibault and Vincent, 1990), and 1995 (Vincent *et al.*, 1995) have allowed for both panel studies (studies of the same speakers over a period of time) and trend studies (re-study of the same community, but not the same speakers). See Sankoff and Blondeau's (2002) report on both trend and panel studies of the changes in /r/ in Montreal. Schilling-Estes (2003) compared data from 1983 and 1991 to examine real-time change in Smith Island, MD. Naro and Scherre (2003) presented a trend study comparing data from the 1980s and from 1999–2000 showing changes in number agreement in Brazilian Portuguese. Other Real Time studies, all cited in Sankoff (in press), include the restudy of Rio de Janeiro (Callou *et al.*, 1998); Cedergren's (1987) restudy of Panama City; Hansen's (2001) trend study of Parisian nasal vowels; Paunonen's (1996) restudy of the 1971 Helsinki survey; and Trudgill's (1988) restudy of Norwich.

Experimental Phonology

R Wright, University of Washington, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

As its name implies, *experimental phonology* can best be described as the application of the scientific method, and therefore the experimental method, to the study of the phonologies of spoken and signed languages. While it has seen a recent increase in popularity, the application of the experimental method to study of phonological phenomena began a little more than a century ago. Künhart and Nolan (1999) describe Scripture's (1902) and others' articulatory experiments in the late 1800s and early 1900s that challenged then widely held views about phonological structure. At the time, Bell's (1867) and Sievers's (1876) introspective studies had led the linguistic community to posit discrete and invariant speech segments (more or less equivalent to phonemes) with brief contextual transitions (the proverbial 'beads on a string'). Scripture, citing evidence of long-distance coarticulation, challenged the division of speech into sequential units such as segments and syllables and instead proposed a simultaneous articulatory plan with continuously varying movements. While methodologies became more sophisticated over time and results more reliable, Scripture's hypothesis foreshadowed the work of Stetson (1951) and aspects of Browman and Goldstein's (1989) articulatory phonology. Nevertheless, while the experimental method has seen continuous application in phonetic and psycholinguistic research into phonological phenomena, it was not widely used by mainstream phonologists until recently.

In its current form, experimental phonology has its origins in the mid–1970s to mid-1980s with the work of Ohala (e.g., 1974, 1986), Jaeger (e.g., 1980), Treiman (e.g., 1983), Beckman and Pierrehumbert

Experimental Phonology

R Wright, University of Washington, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

As its name implies, *experimental phonology* can best be described as the application of the scientific method, and therefore the experimental method, to the study of the phonologies of spoken and signed languages. While it has seen a recent increase in popularity, the application of the experimental method to study of phonological phenomena began a little more than a century ago. Künhart and Nolan (1999) describe Scripture's (1902) and others' articulatory experiments in the late 1800s and early 1900s that challenged then widely held views about phonological structure. At the time, Bell's (1867) and Sievers's (1876) introspective studies had led the linguistic community to posit discrete and invariant speech segments (more or less equivalent to phonemes) with brief contextual transitions (the proverbial 'beads on a string'). Scripture, citing evidence of long-distance coarticulation, challenged the division of speech into sequential units such as segments and syllables and instead proposed a simultaneous articulatory plan with continuously varying movements. While methodologies became more sophisticated over time and results more reliable, Scripture's hypothesis foreshadowed the work of Stetson (1951) and aspects of Browman and Goldstein's (1989) articulatory phonology. Nevertheless, while the experimental method has seen continuous application in phonetic and psycholinguistic research into phonological phenomena, it was not widely used by mainstream phonologists until recently.

In its current form, experimental phonology has its origins in the mid–1970s to mid-1980s with the work of Ohala (e.g., 1974, 1986), Jaeger (e.g., 1980), Treiman (e.g., 1983), Beckman and Pierrehumbert

(1986), and others working at the intersection between phonology and phonetics or phonology and psycholinguistics. The 'Laboratory phonology' series provides an excellent collection of work in this area (Kingston and Beckman, 1990; Docherty and Ladd, 1992; Keating, 1994; Connell and Arvaniti, 1995; Broe and Pierrehumbert, 2000; Gussenhoven and Warner, 2002; Local *et al.*, 2004). A common thread that runs through research in experimental phonology in the belief that evidence is only valid if it is testable, falsifiable, and replicable. An equally important research principle is using methods that minimize experimenter bias.

While it is not diametrically opposed to traditional generative phonology, and certainly not to phonological theory *per se*, experimental phonology does not recognize as **evidence** many of the phonological observations that have been made in the past 40 years. Observations based on introspection are of particular concern because they can neither be controlled nor replicated. Since no other linguist can replicate the conditions existing in another's mind, and since thinking about something necessarily involves bias, introspection will never be a methodological tool in experimental phonology, not even mass introspection, in which a group of linguists all believe that they have the same feelings about a particular phenomenon. This is in contrast to well-designed studies in which the tasks, the stimuli, the subject populations, and so on are controlled to minimize a variety of biases and the experimenter is not a participant in the study itself.

The Scientific Roots of Experimental Phonology

At the scientific method's core are the philosophical underpinnings of skepticism and falsifiability. Skepticism comes from the recognition that all observers are biased in their observations of the world due to their own experiences and beliefs and larger cultural beliefs and norms. Thus, any belief about the world is only as reliable as it is testable. When developing theories, it is therefore necessary to minimize inherent bias through adherence to standard procedures and controlled observation. Any two scientists independently applying the scientific method to the study of phonology and using the same set of measures ideally should replicate each other's experimental results, regardless of their personal beliefs, cultural milieu, or experience with language.

The scientific method's inherent skepticism also means that we, as scientists, cannot know the truth. This means that we cannot prove our hypotheses about language to be true; we can only test them. We accept that a hypothesis is valid only if we have failed to disprove it, but we also recognize that a future linguist may have a competing hypothesis that better accounts for the phonological phenomenon under study. However, a negative result, in other words, a disproved hypothesis, does not imply that some other hypothesis has been validated, only that the tested hypothesis has failed the test and that the result is null. This is because when we test a hypothesis, or even a set of hypotheses, we are by necessity **not** testing the myriad of competing factors that may have resulted in the failure of our test. In any experiment there is always the null assumption that the tested hypothesis has no reliable effect, that is, that there is no useful evidence for any theory or hypothesis.

Observation, Hypothesis Formation, Hypothesis Testing

Pick up any textbook that covers the scientific method and you will see that there are three steps involved in experimental design: careful observation, hypothesis formation, and hypothesis testing. At both the observational and the hypothesis testing stages, the observed data must be quantifiable and statistically reliable. As Ohala (1995) notes, this separates experimental work from other necessary aspects of linguistic science such as description and classification. However, experimental phonologists believe that to be able to form a coherent and rational phonological theory, we must ultimately be able to test the theory's predictions about language in a rigorous and scientific way.

Even at the observational stage, the scientist uses tools that are as objective and controlled as possible. At this point, it is important to understand the limitations of the tools and observational methods. It is equally important to utilize methods that adhere to a set of standards. The same rigor and understanding of the methodological limitations must be applied in the hypothesis testing stage. For example, when even standard transcriptional methods are employed in the absence of acoustic tools, observations are coarse and are affected by perceptual bias on the part of the transcriber. Likewise, in the absence of articulatory tools, when acoustic tools are used to measure how speech articulations occur, they may miss movements that leave no articulatory trace or are obscured or distorted in the acoustic signal. On the other hand, when articulations are measured in the absence of acoustic data, certain aspects of cause-and-effect relationships between the articulations and speech

signal remain obscure. Finally, any claim about an articulatory or acoustic measure and phonological contrasts, phonological units, constraints, processes, and so forth should be tested at some point using a perceptual measure. None of these methodologies are invalid, but it is important to keep in mind that the graininess of the observation determines the degree of resolution in the hypothesis formation and testing stages. Moreover, the hypothesis determines the experimental design, which in turn determines the appropriate methods and appropriate type of data.

A good example of externally imposed limitations in our ability to observe comes in studying infant language acquisition; observation of spontaneous babbling in infants is necessarily limited primarily to audio and video recordings. Therefore we are limited in our observations to transcriptions, simple perceptual tasks, acoustic measures, and what articulatory information may be gleaned by visual observation. As a result, the degree of resolution at the hypothesis formation or testing stage is more limited than that seen in work on adult speech, where more invasive articulatory measures are possible or where task complexity is less of a limiting factor. Fieldwork observation has also been limited to transcription, perceptual tasks, acoustic measures, and visual inspection of articulations (with the exception of static palatography) because most articulatory methodologies have traditionally been limited to the laboratory. Recent advances in noninvasive technologies for articulatory observation, such as ultrasound, may do away with many limitations in articulatory observations of infants or in linguistic fieldwork (e.g., Green *et al.,* 2003 for child language; Gick, 2002 for field methods).

Most phonological language descriptions traditionally were based on speech sounds that had been impressionistically transcribed by a single researcher, were based on a single speaker, and collected under uncontrolled conditions. This is becoming much less common. In this day of affordable and portable digital recorders and computers, there is little excuse for using this kind of data unless the language of interest is no longer spoken. In the event that there are no more speakers of the language left and the researcher must resort to data collected in the past under less than ideal circumstances, the data must be used with caution and given less weight than data collected using more sophisticated methodologies or data that can be verified by the phonologist with speakers of a language.

In the past, similar data collection techniques had been employed in infant studies (e.g., Jakobson, [1941]1968), and in speech error studies (e.g., Fromkin, 1971). The uncontrolled and often anecdotal observational techniques employed in these early studies result in only the coarsest sort of data and should be taken only as a starting point for more controlled observations involving multiple transcribers and a reasonable population sample (e.g., Stemberger, 1991 for speech errors; de Boysson-Bardies *et al.,* 1992 for child language) and usually acoustic measures (e.g., Frisch and Wright, 2002 for speech errors; Buder and Stoel-Gammon, 2002 for child language). Moreover, if the observer wishes to make observations involving speech articulators, then articulatory measures ultimately should be employed (e.g., Mowrey and MacKay, 1990; Pouplier, 2003 for speech errors; Tiede, 1996 for the feature ATR in vowel contrasts).

Selected Examples of Work

The various methodologies and findings in the experimental phonology literature are too numerous and complex to summarize sufficiently in a document of this type. Rather, the work cited here represents a sample that touches on several core areas of phonological theory or on important methodological issues. Ohala (1995) summarizes several areas in which experimental phonology has made a lasting contribution to phonological theory. The field includes experiments on voicing and other laryngeal contrasts (e.g., Lisker and Abramson, 1964; Raphael, 1972; Jager, 1980), assimilation (e.g., Fujimura *et al.,* 1978; Ohala, 1990), sound change (e.g., Ohala, 1974, 1993), and syllable structure (e.g., Treiman, 1983; Cutler *et al.,* 1986).

A recent study by Pouplier and Goldstein (in press) on perceptual bias in speech error observation highlights the danger to phonology of limiting observations to the coarsest level, in this case transcription. Transcriptional data in speech error corpora have led researchers to conclude that, in phonological encoding, speech errors originate from a categorical shift of a segment (or feature) to an erroneous position within a prosodic structure (such as a syllable or word). The reported errors typically have an asymmetric distribution, favoring syllable and word onsets and favoring certain segments over others. However, acoustic and articulatory studies of errors indicate a wide variety of errors that had not been reported in the traditional literature. Pouplier and Goldstein presented listeners with a stimuli containing known articulatory errors. Their results indicate that biases in the perception of errors appear to be the source of asymmetries in error distributions as they have been observed in speech error corpora, particularly those patterns that are used to support coronal underspecification. Moreover, recent research by Stemberger

(2004) using a tongue twister paradigm indicates that speech errors are also sensitive to certain types of lexical effects that are not predicted by traditional phonological theory. For example, phonological similarity (neighborhood) is shown to have faciliatory effects: Fewer errors occur for words with large numbers of neighbors that share the characteristic that is being primed for error, while words do not share the target characteristic have little effect on error rates.

Phonotactic constraints such as the sonority sequencing principle or restrictions on codas have traditionally been regarded as part of the underlying grammar. However, many phonologists have recognized that there appears to be a role for perception in such constraints. One recent study (Wright, 2002) attempted to investigate the potential role of perception in restrictions on codas. He found that place of articulation in coda consonants was perceived with a much lower accuracy than their onset counterparts in noise lending evidence to a perceptual motivation for constraints against codas in general. He also found that certain manners of articulation were affected much more by noise than others when isolated from vowels: In nasals, place was perceived poorly in the absence of vocalic transitions but was rarely lost altogether in noise; stops were often lost completely in noise even though their place was recovered reliably in the absence of noise; and fricatives' place was identified accurately in the clear and in noise. The last finding has a bearing on why sibilant fricatives such as /s/ are frequently found to violate sonority-based constraints.

The role of lexical frequency in phonology, phonological processes, and phonological constraints has remained controversial. Traditionally, most phonological processes or constraints (such as assimilation, vowel harmony, or OCP effects) are regarded as being discrete and not affected by lexical factors such as word frequency or transitional probabilities across words in the lexicon. However, there is evidence from a variety of sources that this view is an oversimplification due in part to lack of controls in observation or hypothesis testing. For example, Coleman and Pierrehumbert (1997) found that wellformedness judgments on neologisms were correlated with the log likelihood of segmental combinations across the lexicon. In a follow-up experiment that was aimed at examining the gradiency of a well-known phonological process, nasal place assimilation, Hay *et al.* (2004) investigated the psychological reality of nasal place assimilation while also exploring the effect lexical frequencies had on the judgments. In a series of three experiments, they presented the subjects with edited stimuli that contained sequences of nasal+ obstruent that either agreed or disagreed in place of articulation and also varied in the log likelihood of occurrence in the lexicon. They found that nasal homorganicity is both psychologically real and gradient in its effect on judgments. Importantly, the patterns that they observed in their data were related to lexical frequency, rather than being an all-or-nothing restriction that must apply equally across all words in the lexicon. This finding is supported by patterns of speech errors in which lexical factors played a role in the probability and types of errors that occurred (e.g., Frisch and Wright, 2002) and by research on language acquisition that finds that the transitional probabilities of segment strings are used by infants in segmenting prosodic structures such as words from running speech (Saffran *et al.*, 1996).

The last three studies are cited because each tests specific predictions that phonological theory makes about how speakers should behave in a given phonological task and because each challenges commonly held views in more traditional areas of phonology. Together with previous experimental research, they raise three important questions for phonologists: What constitutes evidence? How precise do we need to be in our observations of language? Is our theory of grammar based on our biases or on actual patterns in language?

Expletives and Dummies

R Sornicola, Università di Napoli Federico II, Napoli, Italy

Problems of Terminology

Preliminary Considerations

The term 'expletive' covers a wide range of disparate phenomena, whose treatment as one unified group still lacks theoretical basis. Studies in this area are often limited to descriptions and exemplifications of structures that are considered together under the more general label of sentence 'fillers' without clearly definable semantic value. Although in modern linguistics the term 'expletive' has been used since the 19th century in various fields (by the Neogrammarians, by Bréal and Saussure, and by idealist linguists), in contemporary linguistics it is most commonly used with the meaning assigned to it in generative grammar: a "place holder which stands for the subject of the predication when the latter is in postverbal position" (Moro, 1997: 4; cf. also Haegeman, 1991: 53). The role of this type of element is thus defined on a purely structural basis (see the below section 'Expletives and Dummies in Generative Grammar'). 'Pleonasm' and 'dummy' are synonymous terms, often used more or less interchangeably with 'expletive' in the literature of various theoretical and methodological approaches. The latter has a specific meaning in generative grammar (see below).

Two basic issues are of particular interest: (1) How to determine the function(s) fulfilled by expletive units; and (2) how to account for their distribution according to style and register, as in many languages they are characteristic of more informal and spontaneous styles of speech. Both problems have a descriptive and also theoretical dimension. With regard to function, once the types of expletive structure have been identified and their formal properties established, we must examine the specific nature of their meanings and consider whether we can really postulate linguistic forms whose meaning representation is empty. This question raises two important theoretical issues that cannot be avoided. One issue is the status of these structures with respect to the relationship between form and function and to that between function and meaning (see the following paragraphs). The question of stylistic distribution must be addressed by reconsidering traditional explanations based on redundancy and *abundantia*, which are held to be characteristic of spontaneous spoken discourse as opposed to planned written text. These two problems perhaps constitute distinct but complementary aspects of the challenge that spoken discourse and spoken language phenomena pose for current theoretical models. Although expletive units occupy a marginal role in modern linguistic thought, they are of significant potential interest in the development of new models of language and speech, as well as for new linguistic models in general.

History of the Concepts and Problems in Their Definition

The definition of expletive/pleonasm as an empty filler element has its roots in classical rhetoric. The Greek term *πλεονασμός* is present in Dionysius of Halicarnassus and Apollonius Dyscolus with the meaning 'use of redundant words' and 'lengthening of clause,' 'repetition' (cf. Liddell and Scott, 1996: 1416). The Latin adjective *expletivus* appears in the works of Latin grammarians (Servius, Pomponius, Donatus, Priscianus, Charisius), particularly with reference to conjunctions, meaning a part of speech that without altering the sense, "explendi et ornandi causa quasi abundanter additur," 'is added almost abundantly to fill up and embellish' (*Thesaurus Linguae Latinae*, V, 2: 1721, 80ff.). Quintilian considers *πλεονασμός* to be a vice (*soloecismus*) of addition (*adiectionis vitium)* (Quintilian, *Institutio Oratoria*. 1, 5: 40), similar to others such as macrology, perissology, and tautology (cf. Lausberg, 1960, vol. 1: § 502) and distinct from the vice of subtraction (ellipsis) and from that of inversion (anastrophe) (cf. Lausberg, 1960, vol. 1: § 501). Pleonasm occurs when a phrase is overloaded with entirely superfluous words (Quintilian, *Institutio Oratoria* 8, 3: 53; cf. also Lausberg, 1960, 1: § 502). The expression *ego oculis meis vidi* 'I saw it with my own eyes' shows in comparison to the alternative *vidi* '[I] saw [it]' (cf. Quintilian, *Institutio Oratoria* 8, 3: 53) several elements that are unnecessary, in that they are already expressed explicitly or implicitly in the expression constituted solely by the verb form. The pronominal form *ego* could be considered a repetition of the inflectional bound morpheme *-i,* which in the perfect tense is a marker of the first person, and the phrase *oculis meis* expresses explicitly two components of the semantic content of the verb *video*. One is evident in the very definition of 'to perceive with one's eyes'; the other can be extracted through an inference, which is relevant to all verbs that are compatible with an Agent or Experiencer Subject: that the action or the perception expressed is realized through a part of the body of the Agent or Experiencer.

Pleonastic alterations were considered vices of 'diction' (*elocutio*) if they lacked intentional motivation,

but Quintilian notes that they can also be related to emphasis or assertion (*adfirmationis gratia*), as in Virgil's *Aeneid,* Book 4, line 359: *vocemque his auribus hausi* 'and [I] heard his voice with my [own] ears.' This testifies to a basic problem that has affected linguistic thought for centuries, namely, how to define the criteria on the basis of which certain elements of a structure must be considered excessive or redundant. In Quintilian's example, *Institutio Oratoria* 8, 3: 53 as cited above, the verb form *vidi* is considered a semantically compact and omnicomprehensive nucleus, with forms such as the personal pronouns or the peripheral phrase *oculis meis* mere repetitions. In fact, this analysis is only possible if a phrase/utterance is reduced to a minimal structure whose content is expressed by constituent parts necessarily and sufficiently with respect to the referential function. It implies a transformation that takes as its principle the ideal of *brevitas* ('brevity'), considered a stylistic virtue (cf. Quintilian, *Institutio Oratoria* 8, 3: 82). There has been an implicit and straightforward assumption of this operation and the principles behind it in modern studies of phrase structure, in particular in studies of the relationship between the structure of the verb phrase and that of the subject noun phrase (see the below section 'Expletives and Syntax'), and more generally in the definition of a pleonastic/expletive unit. The procedure implies several relevant theoretical assumptions:

1. that for every utterance structure there exists a corresponding structure derived by minimal (i.e., most economical) paraphrase;
2. that this derived structure is the base on which the logicosemantic and syntactic relationships of all expanded paraphrases can be studied;
3. that the informative–referential function should be a priority for structural analysis;
4. that the relationship between function and form should be biunique (one and only form should correspond to each function).

Assumptions (3) and (4) seem particularly open to criticism. As far as (3) is concerned, the importance assigned to the informative–referential function, already questionable under a theory of language functioning, means that all deviations from the minimal structure taken as a standard of comparison may be considered 'emphatic.' It is clear that the logic of the whole theory does not take into account the characteristic properties of linguistic planning, particularly of spoken discourse planning. These may be relevant to understanding not just language functioning but also grammatical structures.

In modern linguistics we must take note of some attempts to replace the concept of expletive/pleonasm with models of various types, the ultimate justification for which would have to be found in psychological phenomena. Paul (1920: § 121) considered pleonasms in negation and other syntactic phenomena involving apparent superfluity to be the effect of "contamination." Schwyzer (1941) suggested a wider model of "hypercharacterization" (*Hypercharakterisierung*), providing a rich range of possible applications for phenomena found in genetically and typologically different languages. According to Schwyzer, the hypercharacterization model should not be defined exclusively on the basis of stylistic phenomena, but should take account of grammatical, morphological, and syntactic factors of varying regularity, such as the structures with reduplication found in several Indo–European languages, or those with subject pronouns adjacent (and in some languages cliticized) to verb forms that are inflected for person. He maintains that the explanation should in general be attributed to the "feeling of insufficient characterization" on the part of the speakers, an idea that had previously been endorsed by Brugmann (cf. Schwyzer, 1941: 27 fn. 3). Although Schwyzer's attempt is certainly interesting, it still relies on the mere idea of repetition of form and/or function, the basis of which is somewhat unsatisfactory.

Types of Phenomena

The phenomena traditionally defined as 'expletive/pleonasm' constitute a wide and varied set. Their examination shows the hybrid nature of the range and the impossibility of identifying a single source factor. In many cases, the terms in question seem to be used simply for want of better descriptions. Heterogeneity already emerges at the simple descriptive level, and it is even more clearly evident if we look for reasons behind the phenomena investigated. A swift analysis of the main types of phenomena grouped together under this label is thus appropriate. These will be divided into three different groups on the basis of the nature of the process that determines them: Expletives/Pleonasms due to:

1. processes of desemanticization (bleaching) typical of grammaticalization paths. These are particularly evident in phenomena that involve constructions with modal or aspectual value;
2. factors more **specifically** connected to planning strategies characteristic of spoken discourse. These are particularly evident in phenomena of pronominal deixis and in their syntactic linearization;
3. metrical and prosodic factors.

This classification should not however be taken as absolute. Indeed, in some phenomena it is possible to

recognize an action connected to two or more causes. For example, the phenomenon of expletive subject pronouns could be considered a result of the grammaticalization of typical strategies of spoken discourse (see below discussion).

It is also possible to categorize different phenomena along the *langue/parole* axis or, to use a different model, according to the level of grammaticalization (*see* **Grammaticalization**). Some phenomena can typically be grouped together at the *parole* level and are thus not grammaticalized, but are of a stylistic nature, even if they conform to more or less frequently occurring schemata. Phrases that constitute etymological figures, such as the often-studied examples in Latin prose (cf. *pulchram pulchritudinem*, 'beautiful beauty,' *incipit initium* 'beginning begins,' *saepe solere* 'to be often accustomed to') (Leumann *et al.,* 1965–1977, 2: 792, 793, 797), are found in casual registers of various languages, whether spoken or written. Other phenomena have a more obviously grammatical dimension, such as the types described here in the following sections. Among the phenomena with a greater level of grammaticalization, one particular case is constituted by *expressions figées*: Think, for example, of pairs of synonyms such as Italian *sano e salvo*, English *safe and sound* (the adjectival pairing is attested in the Latin of Plautus) (cf. Leumann *et al.,* 1965–1977, 3: 786), often with alliteration or rhyme, where a possible original meaning with elative or intensifying value has eventually faded. Between the two extremes of stylistic singularity and grammaticalized constructions there exists a wide range of phenomena in the process of grammaticization. In many cases it can be difficult to establish whether these are stylistic or grammatical. We can consider forms typical of New Testament Greek with duplication of the verb 'to say' *ἔφη λέγων,* lit. 'he spoke, saying' and *ἀπεκρίθη καὶ εἶπεν* 'he replied and said' (cf. Blass and Debrunner, 1976: 349; Kieckers, 1912: 154; Kieckers, 1915: 34ff.), which are also found in medieval Greek and have been retained as calque-expression in Latin translations of the Bible (cf. *sic ait dicens*, *respondit et dixit ei*) and in various modern European languages. As with other verbal periphrases, the wide diffusion of these constructions poses difficulties in outlining their history, especially in identifying the factors that determined their development and spread (cf. 'Auxiliation and Expletivity' below; the coordinating type is present in many Romance dialects and colloquial varieties today). An uncertain level of grammaticalization also seems to be that of another type with wide areal distribution, where the verb 'to say' appears as a parenthesis before or within a reported speech (cf. Latin *inquit* (Petersmann, 1977: 48ff.), Italian *dice* 'she/he says,' dialectal German *segg ik* 'I say' (Havers, 1931: 170); cf. also Schwyzer, 1929: 244). This type seems to be limited to spoken registers.

Sometimes also defined as expletives/pleonasms are constituents whose function is of doubtful theoretical status, such as the so-called 'personal dative' pronouns. In this construction, a personal pronoun coreferential with the subject noun phrase appears, often adjacent or cliticized to the verb, that expresses the meaning 'in the interest of, to the advantage of' or the involvement of the subject in a given action/state: cf. regional Italian of Southern areas *che mi mangio oggi?* 'what do [I] eat for myself today?' (instead of *che mangio oggi?*). This construction is present in a number of Indo–European languages (cf. Havers, 1931: 134), at different levels of grammaticalization. In Slavic languages and in a few Romance varieties, such as colloquial Spanish (cf. Schuchardt, [1884] 1971: 127ff.), the southern dialects of Italy, and Italian spoken in the south (cf. Sornicola, 1997a), this is an entirely regular construction, especially with certain classes of verbs. This type was frequent in spoken Latin (cf. Petersmann, 1977: 83–85 for the language of the *Satyricon*), and in a few epigraphic texts from the Imperial Age it shows a state of incipient crystallization with the 3rd-person reflexive pronoun (cf. Cennamo, 1991). It is also found in some dialectal varieties of American English, such as the Appalachian dialects (cf. *we had us a cabin, built us a log cabin back over there*) (Christian, 1991). The theoretical representation of this type is problematic. Although this form does have some affinities with the indirect object, it cannot be represented with this type of function, since it exhibits specific grammatical properties (for English, cf. Matthews, 1981: 130; Christian, 1991). Furthermore, it is not clear whether or not it can be considered an argument of the verb. It is possible that structures of this kind are considered expletives simply because in linguistic theories there are no models that can be used for their classification.

Effects of Grammaticalization Processes

A considerable number of processes traditionally defined as expletivization can be attributed to processes of grammaticalization. But grammaticalization raises other problems. The first involves the nature of the relationship between expletivization and grammaticalization, and in the end, the very definition of expletive. The simple passage of an element from a semantic to a grammatical function does not necessarily have to involve a process of expletivization, as a function of the unit is in any case preserved. On the other hand, it is doubtful whether elements can be

bleached of meaning to such an extent that they have not functions. Yet in studies of grammaticalization the use of the term 'expletive' or 'expletivization' is not uncommon with reference to developments of a main verb into an auxiliary or 'converb.'

The second problem regards the extreme delicacy of the semantic analyses that are necessary to determine desemanticization and the extent to which it is present. We will discuss these issues in the following sections.

Interjections and Modal Particles

Where modality is concerned, we can observe many phenomena whose properties are the result of processes of desemanticization or other changes in semantic value. In such cases the original etymological meaning has been obscured and the element is close to becoming an expletive/pleonasm. This is typical of modal particles, some of which are developments from early interjections. The resulting structural unit often combines with others of similar meaning, giving rise to an aggregate form in which each of the components conveys an illocutive potential (*see* **Speech Acts**) reinforced by the other, without it being possible to determine which is the specific value of each of the two parts. One example of this phenomenon is offered by the Latin *pol* (< Pollux, Polluces), *edepol* (cf. Ernout and Meillet, 1959–1960: 190b), whose original exclamative value 'by Pollux!' has weakened and become a generic asseverative expression 'indeed! truly!' that often occurs straight after an adverb of equal modal value, such as *certe* 'certainly,' or *sane* 'indeed, by all means': *certe pol (edepol), sane pol* 'indeed, truly.' A similar process is that of the type *Hercle* 'by Hercules!,' which has passed to a purely assertive value and is also found in combination with the modal adverb *vero* 'indeed, truly.' These types of developments are also present in modern European languages. The Italian curse *Diavolo!* 'by the devil!,' may also be found in conjunction with the affirmative adverb *sì*, as a reinforcing form with the value 'certainly yes,' and even alone as an affirmative response: *Sei contento?* 'Are you happy?' *Diavolo!* 'Yes, of course.' A curse may be inserted in a larger enunciative structure as an inert constituent. For example, Italian *Che diavolo vuoi?* and English *What the devil (the hell) do you want?* display a *Wh-* question with a phrase juxtaposed to that of the complementizer, whose semantic value consists purely of an illocutive force of irritation or annoyance.

Auxiliation and Expletivity

Processes of desemanticization that lead to loss of lexical value and in some cases also grammatical function of the constituent involved are characteristic of periphrastic constructions with verbs of movement, verbs in the semantic fields of 'to take' and 'to do.' They are found in many languages of different families (cf. Havers, 1927), in some appearing typically in substandard or dialectal spoken registers (cf. Coseriu, 1966: 16–26). Cross-linguistic comparison presents opportunities for interesting analyses but also poses the risk of grouping certain phenomena together that in fact require different classifications. So, for example, as regards periphrases with verbs of movement, the paratactic type:

> I go/come and X
> (where X is a variable denoting a verb form that assumes the same inflectional person and tense markers of the verb of movement)

is present in various European languages, but with different characteristics with regard to the type of syntactic and semantic relationship between the verb of movement and X. The spectrum of variation includes at one extreme constructions in which each of the two verbs retains a certain level of syntactic and semantic independence with respect to the other (cf. English *I went and said*, Italian *andai e (gli) dissi*). At the other extreme are constructions in which the verb of movement is downgraded to the status of a quasiauxiliary. Such a quasiauxiliary has lost its full capacity not only of semantic but also of syntactic functioning (it cannot undertake any grammatical relation, e.g., it cannot assume an object) and is restricted to expressing an illocutive force of shock, marvel, and/or regret. The phenomenon shows notable similarities with that of converbs. This is exemplified by types such as spoken Spanish *fué y lo hizo*, lit. '[s/he] went/ came and did it,' *va y me dice*, lit. '[s/he] goes and tells me' (cf. Keniston, 1936, particularly 166; Coseriu, 1966: 30), dialectal Italian *vado a ffaccio*, lit. '[I] go and do' (cf. Sornicola, 1976, particularly 71), modern Greek *ἔρχουμι κὶ κάσουμι* (= *ἔρχομαι καὶ κάθομαι*), lit. '[I] come and sit' (Thumb, 1910: 10.2; Seiler, 1952: 159; Coseriu, 1966: 23).

It is doubtful whether the verb reduced to auxiliary or quasiauxiliary status can really be considered an expletive. Of this opinion is Wagner (1956), while Keniston (1936: 166) sees in the first verbal element of the Spanish construction "an intensive used in popular speech, originally with affective values of surprise or irritation." There are good reasons for maintaining that in contemporary Romance and Modern Greek varieties the process of expletivization is by no means complete. This conclusion seems plausible, particularly since within the same variety one specific periphrastic type may, depending on the context, assume different values, some

of which preserve to varying extents traces of the meaning of movement of the quasiauxiliary verb. An interpretation in terms of inchoative/ingressive aspectual value has been proposed by Rohlfs (1949–1954, vol. 3: § 740) and Wagner (1956) (analysis criticized by Coseriu, 1966: 43; Sornicola, 1976: 71), while Keniston (1936: 167) maintains that a possible original inchoative value has been lost and that the verb now has a solely intensifying function.

Similar considerations are relevant to paratactic periphrases with verbs of the lexical class of 'to take' (cf. Coseriu, 1966), exemplified in constructions such as English *she took and died*, Spanish *tomo y me voy*, Italian *prendo/piglio e me ne vado*, lit. '[I] take and go away' (Coseriu, 1966: 17, 21, 23), Modern Greek *πιάνει καὶ χτίζ'ἕνα σπίτι*, lit. '[he] takes and builds a house' (cf. Seiler, 1952: 159; Coseriu, 1966: 23). The desemanticized verb is restricted to expressing the idea of "sudden resolve, schneller Vollzug," or an aspect of "plötzliche oder unerwartete Handlung" (Coseriu, 1966: 42). These functions fade into one another and are difficult to define. Furthermore, it is not clear whether verbs that have lost their lexical value may be defined as quasiexpletives. Such a conclusion seems plausible, however, when the verb has reached complete desemanticization, with loss of inflection and fossilization, such as the construction in Italian dialect of Otranto *sta bbegnu*, lit. 'be.PRES. [I] come,' = 'I come.' In this type an invariable form of 'to be' (*stare*) precedes all conjugated forms of the full verb, and the whole construction alternates with the simple full verb with no difference in meaning (cf. Meyer-Lübke, [1890–1906] 1974, vol. 3: 591–592).

A development toward the fossilization of the verb 'to do' in a periphrasis:

to do + X
(where X is a variable that denotes a infinitival verb form)

into a simple grammatical marker can be found in English in the diachronic development of *do* (cf. Traugott, 1972: 138–142; Stein, 1990; Nurmi, 1999; and the extensive bibliographies cited in these works). Such a grammatical marker is present today in interrogative, negative, and contrastive-emphatic declarative structures (cf. Quirk *et al.,* 1985: 2.49–51, 3.36–37; the development is already outlined in early Modern English: cf. Traugott, 1972: 138; Stein, 1990: 11–13).

Examination of these developments over a long period offers interesting points for consideration. Two functions of *do* – the causative function and that which is "periphrastic and devoid of meaning" (the terminology is from Traugott, 1972: 199) – seem to have coexisted in Middle English (cf. Denison, 1985: 46–48; Stein, 1990: 11ff.; Nurmi, 1999: 22). According to Traugott, values of *do* that can be expressed as 'truly, indeed' and the optional tense marking' function belong in this category. But problems arise from this description. Stein (1990: 11) maintains that functions devoid of meaning should not be hypothesized here, and proposes that the periphrases of Middle English should be interpreted with a semantic value similar or close to a causative. The difficulties in determining exact function are largely outlined in the bibliography (cf. Ellegård, 1953: 29; Denison, 1985: 46; Engblom, 1938; Stein, 1990: 11ff.; Nurmi, 1999: 18). No less significant problems emerge in ascertaining emphatic value (cf. Tieken, 1987: 118; Stein, 1990: 272), which can be identified with reasonable level of certainty only from early Modern English onwards (cf. Traugott, 1972: 199; Stein, 1990: 273).

The occurrence of this type in many languages, particularly in substandard and/or dialectal registers and in periods in history when the rules of the written language were still weakly codified, leads us to believe once again that this may be a natural syntactic change, typical of spoken registers. The type is present in other Germanic languages; German *tun* + infinitive appears at the substandard and dialectal level and in noncontemporary literary texts (cf. Behaghel, 1923–1924, vol. 2: § 746; Russ, 1999: 116, 495) and is also attested in non–Indo-European languages (cf. Havers, 1927). However, while there exists a broad consensus on the origin of periphrastic *do* in spoken registers (cf. Rissanen, 1991: 321; Stein, 1990: 91), it is not clear how the natural syntactic character of these constructions has interacted with other structural and social factors in grammaticalization/grammaticization of modern forms (cf. Stein, 1990: 316–318, 324–328).

Particularly interesting in this respect is the problem of the relationship between the periphrases of Middle English, with semantically weakened *do*, the contrastive-emphatic types of early Modern English, and the modern forms with grammaticalization/grammaticization of *do* in interrogative, negative, and emphatic-contrastive structures. One factor of natural development could have been the affinity or contiguity of emphatic, interrogative, or negative function, which can be seen in the paths of grammaticalization in many languages (cf. Stein, 1990: 275–276; Nurmi, 1999: 29). The association of these functions would therefore have followed the well-known path of demarking of emphasis or contrastivity, leaving *do* behind as a mere 'dummy.' It would, however, be preferable to consider such an element as a hypercharacterization of those functions.

The more controversial issue, however, is the relationship between the early periphrases, with apparently

meaningless *do*, and the more modern declarative types, emphatic or otherwise. Stein (1990: 11) maintains that "although there appears to be an unbroken syntactic continuity, there is semantically a watershed between the earlier 'meaningless periphrastic' and the later use in declarative sentences in Standard English." In this respect analytical difficulties are presented by the modern situation, which is far from uniform, just as they are by earlier phases in the development of the language. In present-day spoken language the emphatic value occurs four times more frequently than it does in the written language (cf. Nevalainen and Rissanen, 1985). The use of *do* in constructions in religious or legal contexts (such as *I do solemnly declare*, or *we, the undersigned, being of sound mind, do this day hereby bequeath*: cf. Quirk *et al.,* 1985: 3.37) is an archaism, which may be attributed to an obvious process of freezing of emphasis as a result of ritualization (cf. Stein, 1990: 272). The periphrastic value "equivalent to the simple tense" (*Oxford English Dictionary,* 1989, vol. 4: 905c) appears only at the substandard and dialectal level (in dialects of southwest England): cf. Ihalainen (1991). This situation is reminiscent of the well-known continuous diachronic development, whereby a stigmatized construction has disappeared from the written language but remains in spoken registers. However, as with periphrastic constructions with verbs of movement and of the semantic area of 'taking,' it is doubtful whether *do* can today be considered a dummy. Although the dialectal forms have been described as interchangeable with the simple verb forms, more accurate analyses indicate that we do not in fact find free variation. These forms instead express habitual or 'generic' aspect (cf. Ihalainen, 1991: 154, 156–159), with similar or contiguous aspectual values to those found in periphrases with *tun* in some German dialects (cf. Stein, 1990: 138; Russ, 1999: 116).

Negation

A different range of grammaticalization processes that are the source of units considered expletives can be found in negation and its determinants. Double negation (reinforced negation) is a phenomenon of natural syntax (cf. Horn, 1989), with typical broad diffusion across genetically and typologically different languages (for Bantu languages, cf. Nurse and Philippson, 2003; for Semitic languages, cf. Brockelmann, 1908–1913, vol. 2; Leslau, 1995). As with periphrastic forms, in languages that are sensitive to difference between spoken and written norms, double negation surfaces especially in spoken substandard and dialectal registers, and tends to be stigmatized in written ones: cf. substandard English *I don't see nothing* 'I do not see anything,' colloquial and dialectal German *Er tut niemand nichts* 'he does not make anything for anybody' (cf. Jespersen, 1917; Milroy and Milroy, 1993; Behaghel, 1923–1924, vol. 2; Wackernagel, 1920–1924, vol. 2). In Italian, as in other Romance languages, double negation is a regular construction in standard spoken registers: cf. *non vedo niente* 'I do not see anything,' while the types without double negation, such as *non vedo alcunché/alcuna cosa*, are typical of the written language.

The diffusion of this phenomenon also in older diachronic phases of modern and classical languages (cf. Plautus: Men. 1027: *nec meus servus numquam tale fecit*) is further evidence of it being the reflex of a very general factor. Yet the nature of this factor needs further elucidation. Whether it is related to the greater difficulty in understanding the more marked negative constructions (cf. Horn, 1989: 154–203) or to a process of emphasis freezing is not clear. Jespersen (1917: 71) maintains that "double negation arises because under influence of a strong feeling the two tendencies . . . one to attract the negative to the verb as a nexal negative, and the other to prefix it to some other word capable of receiving this element, may be both gratified in the same sentence." As to the latter hypothesis, however, it can be observed that the tendency towards syntagmatic expansion for operators of negation is not necessarily connected to emphatic processes. Wackernagel (1920–1924, vol. 2: 299) attributes the doubling of negation to the "need of spreading negation over the whole sentence" (cf. also Jespersen, 1917: 71), a description that suggests automatic structural mechanisms in speakers, but seems weakened by an element of circularity.

Some phenomena pose interesting semantic problems of relationship between negation and certain lexical verb classes. In ancient and modern Indo-European languages, the use of an expletive operator of negation is indeed widespread in complex sentences whose main clause exhibits a verb such as 'to fear' 'to prohibit,' 'to deny.' A well-known example is the Latin type *timeo ne veniat* 'I fear that [s/he] comes,' grammaticalized in the classical period (cf. Leumann *et al.,* 1965–1977, vol. 2: 534). The negative feature inherent in the complementizer *ne* is obviously at odds with the affirmative meaning of the subordinate construction it introduces. The traditional explanation is that this is due to contamination and integration into one sentence of two structures originally linked by parataxis, such as *timeo* '[I] fear' and *ne veniat!* 'may [s/he] not come!' This implies a reanalysis of the negating particle *ne* from a constituent belonging to the clause with the ottative modality into a complementizer governed by the main verb. In the same way, the later type *timeo ne non veniat!* 'I fear that [s/he] does not come,' with an apparent overabundance of negating constituents, would be

due to the integration of two structures, the grammaticalized *timeo ne* 'I fear that' and *non veniat* 'I wish [s/he] does not come' (cf. Wackernagel, 1923–1924: 277ff.; Schwyzer, 1941: 11). The presence of similar phenomena with the same classes of verbs in other modern European languages could be due to Latin influence in learned registers: cf. French *je crains que tu ne sois malade* 'I fear that you are ill' (lit. 'that you are not ill'). Although such construction is not common in German, a few examples can be found, probably due to a calque: *ich fürchte, dass nicht . . . eure Sinne verrückt werden* 'I fear that . . . your senses go mad,' lit. 'that your senses do not go mad' (Luther 2, Cor. 11: 3; cf. Wackernagel, 1923–1924, vol. 2: 278). For negation with verbs of prohibition or impediment (cf. Behaghel, 1923–1924, vol. 2: 87–88).

Comparative structures also often feature negations that have been considered expletives, in both spoken and written registers: cf. German. *ich bin kränker, als du nicht denkst* 'I am more ill than you think,' lit. 'than you do not think' (cf. Behaghel, 1923–1924, Vol. 2: 89), Italian *ti vuole più bene di quanto tu non creda* '[s/he] loves you more than you think,' lit. 'more than you do not think,' French *il est plus riche qu'il ne semble* 'he is richer than he seems,' lit. 'than he does not seem' (cf. Lerch, 1925, vol. 1: 77). Cf. further Havers (1931: 134). Wackernagel (1923–1924, vol. 2: 307) maintains that "to negate what has been backgrounded with a comparative clause is a spontaneous process which recurs at various times." A similar justification could be extended to negation in affirmative temporal subordinates, such as Italian *bisogna aspettare finché non viene* 'one needs to wait until [s/he] comes,' lit. 'until [s/he] does not come' (Rohlfs, 1949–1954, vol. 3: § 970) and in German (cf. Behaghel, 1923–1924, vol. 2: 89–92). But the general factor at work here seems to require further clarification.

An interesting case is that whereby originally reinforcing elements, which in various languages have eventually become grammaticalized as constituents of the negation phrase, lose their etymological value. These are often discontinuous constituents with respect to negation proper, as in Romance examples such as French *je ne mange pas* 'I do not eat,' *il ne vient mie* 'he does not come,' Italian *non costa mica tanto* 'it does not cost so much,' (Tuscan) *non dubito punto* 'I do not doubt a bit' (cf. Meyer-Lübke, [1890–1906] 1974, vol. 3: 774–775; Grevisse, 1975: 946–947; Gadet, 1992: 77–79) or English examples as *I don't like it a bit*. Such constructions show the development of a noun phrase, which originally had the function of an internal object or of a circumstantial element expressing a quantity, into hypercharacterizing negative expressions. These then often fossilize as the normal determiners of negation. The nominal elements involved in this development all share the semantic property of denoting a small quantity. This path is most evident when we look at the Latin origins of the Romance types: French *mie,* Italian *mica* < Latin MICA, 'crumb' (Italian *brisa*, often found as a negative intensifier in Northern Italian dialects, has the same meaning), French *pas* < Latin PASSUS 'a step,' or more specifically 'a measure of length, consisting of five Roman feet,' Italian *punto* < Latin PUNCTUM, 'a point, a small spot' or more specifically 'a small part of any thing divided or measured off; a small weight, a small liquid measure; a small portion of time, an instant, a moment' (Lewis and Short, 1987: 1491–1492). These developments can be seen as the reanalysis of objects or measure adverbials; from being arguments or circumstantials in verb phrases, they become mere determiners of negation inside negation phrases. Sometimes, as in French or in northern Italian dialects, they undergo further developments whereby they can be analyzed as the head of the negation phrase. This change is concomitant with the disappearance of negation itself, as in spoken French *je mange pas*, spoken northern Italian *mangio mica* 'I do not eat.' For a crosslinguistic study of the problem, see Bernini and Ramat (1996).

Expletives and Syntax

Expletives and Dummies in Generative Grammar

In the last 20 years, particular attention has been paid to the syntactic dimension of expletivity, particularly in generative grammar. In this field, the issues of main concern have been the positions occupied by elements considered dummies (i.e., "semantically empty" and "mere slot fillers" (Haegeman, 1991: 53)) in certain syntactic configurations, their relationship with the INFL phrase and its head, their argumental and functional status (for recent perspectives, see the papers in Svenonius, 2002). Particularly under examination have been:

- pronouns in structures with extra-posed sentences (such as English *it is appropriate that he goes*);
- pronouns that precede the verb phrase as substitutes for the subject noun phrase in postverbal position (such as French *il sont venus trois garçons*);
- pronouns in existential-locative structures (such as French *il y a trois garçons*);
- subject pronouns in constructions with meteorological verbs (such as English *it's raining,* French *il pleut*, German *es regnet*).

These pronouns, entirely devoid of referential features, are considered nonarguments, as they behave as substitutes for a constituent endowed with grammatical function, which should be found in that position and therefore simply occupy space in the sentence structure. One should note that the dummy substitute of a subject NP does not necessarily have to be a nominal proform. In existential–locative constructions in English (*there are two cats in the garden*) or Italian (*ci sono tre gatti nel giardino*), the substitute is an adverbial pro-form defined as a subject (cf. Haegemann, 1991: 54–55; Svenonius, 2002: 5).

In generative theory expletive subjects are considered characteristic of non–prodrop languages (such as English, German, and other Germanic languages) in which the position of the preverbal subject must obligatorily be occupied by a constituent, while in prodrop languages (such as Italian and Spanish), it does not necessarily have to be filled (cf. Chomsky, 1981; Cardinaletti, 1994). The dichotomy between prodrop and non–prodrop has been widely employed in typology, in correlation with other parameters (for example the absence or presence of morphologically realized verbal inflection for person). But this purely taxonomic model cannot account for the synchronic and diachronic dynamics whereby some languages reach the state of grammaticalizing/grammaticizing subject pronouns while others do not (cf. Sornicola, 1997b).

Subject Pronouns, Spoken Discourse Strategies, and Processes of Grammaticalization

The spoken registers of languages that are traditionally considered prodrop are rich in various types of constructions with subject pronouns (henceforward SP). This is also true in languages, such as the Romance and Slavonic ones, that have a rich inflectional morphology (a factor often believed associated to optionality of SPs). Constructions of the type SPs + verb with morphological inflection (cf. It. *io dico* 'I say,' *tu dici* 'you say') are highly frequent in the spoken language, under various structural and textual conditions (for Italian and Spanish cf. Sornicola, 1996; for Russian, cf. Fougeron, 2003). In particular, 1st- and 2nd-person SPs have the highest recurrence. Although these forms have been variously described as emphatic or related to switch reference strategies (cf. Hofmann, 1951: § 95, Pinkster, 1987 for Latin), such accounts can represent only a part of the cases that appear in text corpora. In many tokens the SPs may be considered units on the way to becoming grammaticalized, since they have neither emphatic nor switch-reference function (cf. Sornicola, 1994 for Italian; Sornicola, 2002 for Latin and late Latin). Clearly, however, they cannot be represented as grammatical inflection markers, as in French.

Like other phenomena of so-called expletivity, these cases are not easily accommodated in traditional frames, in which all doublings of a given category are considered pleonasms, since they repeat information already contained in that category. But how is the main category chosen? The general frame has a long history behind it, since it was already present in classical rhetoric (see the previous discussion) and taken up again in various forms by the comparative linguistics of the 19th century (cf. Delbrück 1893–1900, vol. 3: 461), by structuralism (cf. Bally, 1932: 153–156), and ultimately by generative grammar, where the relationship between SP, verb phrase and INFL phrase has given rise to wide debate (cf. Safir, 1985; Cardinaletti, 1994; Svenonius, 2002). In these discussions it has been assumed that there is only one head that carries INFL and that possible coreferential units are in various ways treatable as bound elements of an anaphoric chain (cf. Safir, 1985). But the extent to which these models could satisfactorily represent the wide range of structures with SPs is debatable. For example, it is not clear what dependency relationships should be postulated between verbal inflection and pronouns in the Romance and Slavic constructions described above. A more general problem concerns the condition of unique assignment of θ-roles (see Haegeman, 1991 *passim* for an overview and 52–53 in particular for its application to expletive subjects). Whatever its theoretical elegance and even necessity, it is not certain whether it could be stretched to cover the whole area of existing pronominal structures.

Some of these structures, in fact, can be attributed to the general tendency in the spoken registers of various languages towards referential hyperdetermination, which presents itself in the form of propagation of deictic features (cf. Sornicola, 1996). Although needing theoretical refinement, the notion of hypercharacterization (see discussion above) could be perhaps a point of departure for the analysis of the structures under discussion.

Phenomena Due to Prosodic Factors

Also defined as expletives/pleonasms are a few phenomena whose nature is clearly prosodic. These are total or partial reduplications of stems, or insertions of paragogic elements. Such cases presumably have an ultimate phonostylistic origin. Indeed, they often appear as allomorphs or lexical forms that are stylistically and/or sociolinguistically marked. However, they often give rise to fully grammaticalized structures. Although different processes may be at work behind the various phenomena of this range, they

can be considered effects of a general and integrated tendency toward the expansion of word structure, in connection with lexical prosodic (in particular accentual and metrical) factors, and/or syntactic and prosodic environmental conditions. Monosyllabic words such as pronominal forms and conjunctions, or oxytonic words, are often involved. Furthermore, in many languages the final position of intonational block and, to an even greater extent, that of the utterance constitute typical contexts for the phenomena under examination. The accentual conditions are also crucial: In some contexts, among which are those already mentioned, the accent-bearing syllables tend to acquire 'volume' or weight via reduplication or coalescence of another element, like particles desemanticized to a greater or lesser extent.

Latin has a few pronominal forms with stem reduplication, which have been associated with emphasis: cf. *tute* 'you' < *tu* + *te* (Hofmann, 1951: § 95), *mēmē* 'me' < *me*, *tētē* 'you.OBL' < *te*, *sēsē* 'himself' < *se* (cf. *Thesaurus Linguae Latinae*, V, 256: 1721, 75ff. s.v. *ego*; Leumann *et al.*, 1965–1977, vol. 1: 464, vol. 2: 174). The tendency for monosyllabic elements to accumulate in pronominal forms can also be observed in forms such as *egomet, nosmet, illemet*, characteristic of early comedies and of texts where vulgarisms and colloquialisms are frequent, such as the *Satyricon* (Stefenelli, 1962: 123) (on the whole issue, cf. Wackernagel, 1953; Havers, 1931: 179). The predilection for longer pronominal forms (reduplicated or with the addition of a paragogic element) is found, for example, in many varieties of old and modern Romance languages, especially dialectal. Here are a few examples from the Italian area: Apulian *jojə* 'I,' < *jo* 'I'+ *je*; the forms of central and southern Italian dialects *mene* 'I.OBL' (< *me* + *ne*), *tene* 'you.OBL' (< *te* + *ne*); the old Italian and now dialectal form *ene* 'is' (< *è* 'is' + *ne*); monosyllabic forms of adverbial particles of affirmation and negation, like *sine* (sì, 'yes' + *ne*), *none* (*no* + *ne*); infinitives like *amanə*, 'amare,' *avenə*, 'avere,' with the coalescence of a particle onto originally oxytonic forms (*amà*, *avé*); the interrogative adverb *pəkkenə* 'because/why,' derived from truncated forms *pəkké* + *nə* (cf. Rohlfs, 1949–1954, vol. 3: § 336).

It is possible to consider these phenomena similar to vocalic or consonantal lengthening in a stressed environment. Like the latter, these can be explained by the interaction of prosodic and segmental structures: Both the geminate and the agglutinated elements can be considered expansions determined by the prosodic skeleton of the word (cf. Kager *et al.*, 1999).

A specific issue concerns the utterance (or sentence) initial position. In various languages this tends to be reinforced by the combination (and in some cases agglutination) of conjunctions or particles to a pronominal element, even when the conjunction does not seem semantically required, as in late Latin types *atque ego*, *et ego* (cf. Havers, 1931: 9). Other structures that at least in part may be determined by the prosodic and syntactic environment are main declarative clauses with a complementiser in 1st position, as in Romance types with initial *che, que*: cf. Abruzzese *ca mo ve* 'now [s/he] comes,' lit. 'that [s/he] now comes' (Rohlfs, 1949–1954, vol. 3: § 794), Gascon *qu'a yelàt* ' it's freezing,' lit. 'that [it] has frozen,' *que-t dechàm soul* '[we] leave you alone,' lit. 'that [we] leave you alone' (cf. Rohlfs, 1970: 205). In Standard Italian, *che* appears after adverbs of affirmation or negation, as in *sí che l'ho visto, no, che non l'ho visto*, with a reinforcing value (cf. Rohlfs, 1949–1954, vol. 3: 794).

Presumably multiple factors cause conjunctions to accumulate at the beginning of utterances, a phenomenon that can be observed in many languages. The need to fill the first position with constituents with prosodic weight may be in part responsible for various syntagmatic combinations of light adverbs or particles, as in the Latin types *nam et, sed et*. It may also cause conjunctions to be strengthened by coalescing with other particles (cf. Meillet, 1921–1928, vol. 1: 164–165, 171). On the other hand, semantic factors such as intensive redetermination can also play a role. This often leads to the joint use of two adverbs with the same meaning, such as in the (non-classical) Latin types *sed autem,* Italian (substandard) *ma invece* 'but.'

Conclusions

This examination of structures traditionally considered expletive/pleonastic may have demonstrated the extent to which phenomena with different properties and explanations have been grouped together under this label. Behind the apparently unitary tendency toward structural hypercharacterization (i.e., multiple determination of form and function), we have tried to discern heterogeneous processes. Their scrutiny brings to light different properties with respect to the time factor. Some in fact have a dimension that is principally panchronic (that is, they are connected to factors that act independently in many periods and many places), others diachronic, still others synchronic. In the first group we may place the spread of negation in the utterance, subject pronouns with verbs inflected for person, and the increase in the prosodic weight of a word. In the second group, we may place the bleaching of meaning typical of grammaticalization (as in auxiliaries in periphrasis) and, more generally, the survival of archaisms or fossilized

relics in constructions to which speakers are no longer able to assign meaning, and that are sometimes redetermined (such as in Spanish *conmigo* 'with me,' *contigo* 'with you,' etymologically related to late Latin types CUM MECUM, CUM TECUM). Other factors that may lead to phenomena considered expletives have a clearly synchronic origin in processes of contamination and more generally in associative processes (cf. Havers, 1931: 174; Paul, 1920: § 121).

The existence of several structural and historical reasons for phenomena considered expletives allows us to abandon the traditional perspective according to which they are no more than 'illogical' manifestations (thus Wackernagel, 1920–1924, vol. 2: 306). One obvious property of form appears in all structural cases discussed in the third through fifth sections above. It is the expansion or propagation of form within a given phrase and even beyond, in the sentence/utterance. This constitutes a link across different types of phenomena. Yet the implications for theories of sentence/utterance structure are not as obvious.

A few problems of a theoretical nature seem particularly interesting that are related to the concept of function and to the very legitimacy of the notion of expletive/pleonasm. With regard to the first problem, two conclusions may be suggested:

1. It is appropriate to distinguish between semantic function and functioning in discourse. Units exist that do not have semantic function but that do have a functioning power in the utterance, such as those determined by prosodic factors (cf. "Phenomena Due to Prosodic Factors," above). Other units may have both functioning power and semantic function, such as subject pronouns with verbs inflected for person, or the constituents of double negation in nongrammaticalized types. These may be properly defined as hypercharacterized structures.
2. The relationship between function and form on the syntagmatic level must be conceived as plurivocal (more than one form can correspond to each function). This may run contrary to principles or conditions long established in theories, but seems an option that cannot be ruled out.

Some conclusions may also be drawn regarding the legitimacy of the concept of expletive/pleonasm. As we have observed, hypercharacterization is simply the effect of synchronic (or panchronic) processes typical of discourse structuring, which can become grammaticalized or otherwise, or it may be the result of diachronic processes of desemanticization, fossilization, often (although not exclusively) connected to the previous ones. Fossilization with total loss of meaning is difficult to ascertain in many cases. One therefore can have good reasons to think that the concept of expletive has a weak empirical and theoretical basis. A more radical and perhaps paradoxical conclusion would be that expletives (empty elements, or as they have sometimes been called, 'junks') exist neither at the discourse level nor at the *langue* level. But the phenomena that the term has traditionally come to define are notable both at the empirical and the theoretical level.

One final problem concerns the sociolinguistic dimension. It has been widely noted in the literature of various orientations that expletives and pleonasms are typical of the language or style of less educated people. This empirical observation still lacks articulate and stringent justification, but for the moment it is sufficient to maintain that speakers with minimal or no education provide evidence of dynamics of functioning in discourse that cannot be neglected by general linguistic theories.

Expression Meaning versus Utterance/Speaker Meaning

A Bezuidenhout, University of South Carolina, Columbia, SC, USA

© 2006 Elsevier Ltd. All rights reserved.

When Mrs. Malaprop in Richard Sheridan's play *The Rivals* says to her niece Lydia Languish "don't attempt to extirpate yourself from the matter," she means to say that her niece should not attempt to *extricate* herself from the matter. But that is not what 'extirpate' means in English (at least, it is not a meaning one would find listed under 'extirpate' in a good dictionary of English usage). Malapropisms of this sort are one way in which expression meaning (i.e., word or sentence meaning) can come apart from speaker meaning. Mrs. Malaprop has a mistaken belief about what the words she is using mean in the language she is using. Slips of the tongue (e.g., saying 'pig vat' instead of 'big fat') represent another way in which expression and speaker meaning can come apart.

Gricean conversational implicatures represent another, much larger, class of cases in which these two kinds of meaning come apart. These are cases in which the speaker engages in some form of indirection, where, typically, the main conversational point is something implicitly communicated rather than explicitly expressed. In such cases, the speaker's words mean one thing, but the speaker is trying to convey another meaning, either in addition to the literal expression meaning or in place of it. An example of the former sort is when Mary replies to Peter's offer to take her to the movies that evening that she will be studying for an exam then. Mary has explicitly said that she will be studying, but has implicitly communicated that she is refusing Peter's invitation. Here both the explicit statement and the implicit refusal are intentionally communicated. The

Abstract:

Under the term 'expletive,' phenomena with different properties and explanations traditionally have been grouped together. Three main sources of expletives have been identified here: (1) processes of desemanticization typical of grammaticalization paths; (2) factors more specifically connected to planning strategies characteristic of spoken discourse; and (3) metrical and prosodic factors. In some phenomena it is possible to recognize an interplay of these factors. Among the phenomena related to source (1), the loss of full meaning of one of the verbs of a verbal periphrasis is especially conspicuous. Phenomena like double negation and so-called 'expletive subject pronouns' originate in source (2), although they are often also involved in grammaticalization processes leading to them being fixed as normal structures in the linguistic system. Stem reduplication and other kinds of extensions of morphological units are related to metrical and prosodic factors. It is claimed that these disparate phenomena also have various properties with respect to the time factor (i.e., some are mainly diachronic, others synchronic, still others panchronic). They also pose interesting theoretical problems for the form–function relationship. A notion that seems useful at the descriptive level and seems to have potential implications for the theory is hypercharacterization (i.e., multiple determination) of form and function. Two conclusions may be suggested. The first is that it is appropriate to distinguish between semantic function and functioning in discourse. Units exist that do not have semantic function but do have a functioning power in the utterance; other units may have both functioning power and semantic function. These may be properly defined as hypercharacterized structures. The second conclusion is that, contrary to principles or conditions long established in theories, the relationship between function and form on the syntagmatic level must be conceived as plurivocal (more than one form can correspond to each function).

Biography:

Rosanna Sornicola is Professor of General Linguistics at the Department of Modern Philology of the University of Naples Federico II, where she is also the Director of the European Master's Degree in Linguistics. She graduated in Linguistics and Modern Philology at the University of Naples in 1975. She was Visiting Fellow at Wolfson College (Cambridge) in 1983 and Visiting Scholar in 1997, Visiting Researcher at the Department of Linguistics of the University of California (at Berkeley) (1985), and Visiting Researcher at the Department of Italian of the University of California (at Los Angeles) (1988). She is a senior member of Wolfson College of the University of Cambridge. She was Visiting Professor at the University of California at Los Angeles (1990), Manchester University (1990), Girona (1996), and Gand (1999), and has lectured in many other European universities.

She has worked for several international research projects (the EUROTYP project of the European Science Foundation, 1990–1996; the project on Diachronie, diatopie, diastratie, diaphasie des langues romanes directed by Eugenio Coseriu and Rika Van Deyck, 1993–2001) and is currently involved in various research projects on Italian sociolinguistics and dialectology in cooperation with the Department of Linguistics of the University of Turin and the Romanisches Seminar of the University of Heidelberg.

She is member of the scientific board of the reviews *Cahiers de linguistique romane, Lingue e Linguaggi,* and *Revue de linguistique romane*, and is co-editor of the journal *Bollettino Linguistico Campano*. She has been member of the Executive Committee of the International Society for Historical Linguistics, of the Scientific Bureau of the Societé internationale de linguistique et philologie romanes, and from 1999 until 2003 served as President of the Società di Linguistica Italiana.

Her research interests concern phonetic, phonology, syntax, and pragmatics of spoken language, the relationship between spoken and written discourse, Italian and Romance sociolinguistics and dialectology, synchronic and diachronic typology, and history of linguistics (especially the history of European functionalism).

Her publications include the following books: *La competenza multipla* (Napoli, Liguori 1977), *Sul parlato* (Bologna, Il Mulino 1981), *Il campo di tensione. La sintassi della Scuola di Praga* (coeditor with Aleš Svoboda, Napoli, Liguori 1992), *The virtues of language: history in language, text and literature* (co-editor with Dieter Stein, Amsterdam, Benjamins 1998), *Stability, variation and change of word order patterns over time* (editor with Erich Poppe and Ariel Shisha Ha-Levy, Amsterdam, Benjamins 2000), *Langue écrite, langue parlée dans le passé et dans le present* (co-editor with Rika van Deyck and Johannes Kabatek, Gand, Communication and Cognition, 2005). She is also author of many articles published in books and journals.

Expression Meaning versus Utterance/Speaker Meaning

A Bezuidenhout, University of South Carolina, Columbia, SC, USA

© 2006 Elsevier Ltd. All rights reserved.

When Mrs. Malaprop in Richard Sheridan's play *The Rivals* says to her niece Lydia Languish "don't attempt to extirpate yourself from the matter," she means to say that her niece should not attempt to *extricate* herself from the matter. But that is not what 'extirpate' means in English (at least, it is not a meaning one would find listed under 'extirpate' in a good dictionary of English usage). Malapropisms of this sort are one way in which expression meaning (i.e., word or sentence meaning) can come apart from speaker meaning. Mrs. Malaprop has a mistaken belief about what the words she is using mean in the language she is using. Slips of the tongue (e.g., saying 'pig vat' instead of 'big fat') represent another way in which expression and speaker meaning can come apart.

Gricean conversational implicatures represent another, much larger, class of cases in which these two kinds of meaning come apart. These are cases in which the speaker engages in some form of indirection, where, typically, the main conversational point is something implicitly communicated rather than explicitly expressed. In such cases, the speaker's words mean one thing, but the speaker is trying to convey another meaning, either in addition to the literal expression meaning or in place of it. An example of the former sort is when Mary replies to Peter's offer to take her to the movies that evening that she will be studying for an exam then. Mary has explicitly said that she will be studying, but has implicitly communicated that she is refusing Peter's invitation. Here both the explicit statement and the implicit refusal are intentionally communicated. The

statement is intended to give Mary's reason for her refusal. An example of the latter sort is when Mary responds to Peter's refusal to help her when she is in need by saying 'You're a fine friend!' Here she is implicitly communicating that Peter is *not* a good friend. Her words 'fine friend' are being used sarcastically, and she does not intend to communicate what her words literally mean.

It should be mentioned that there are philosophers who think that even what is explicitly said (as opposed to implicitly communicated) can come apart from literal sentence meaning. These are cases where literal expression meaning must be pragmatically narrowed or broadened in order to arrive at what is explicitly communicated. Thus, when Mary says to the waiter at the restaurant that he should take her steak back because it is raw, she doesn't mean to say the steak is literally uncooked, but that it is too undercooked for her taste – a case of pragmatic broadening. Or when Mary tells her son that he is not going to die when he comes crying to her with a cut on his finger, she means to say that he is not going to die from that cut, not that he is never going to die – a case of pragmatic narrowing (*see* **Pragmatic Determinants of What Is Said**).

For some, utterance meaning is just a variety of speaker meaning. It is the meaning an expression has as used by a speaker in some conversational context. The hearer arrives at an understanding of utterance meaning by combining literal expression meaning with other contextually available information, including information about the speaker's communicative intentions. However, at least some philosophers of language and linguists wish to draw a contrast between utterance and speaker meaning. Levinson (1987, 1995, 2000) has argued for three levels of meaning. There is expression meaning, utterance meaning, and speaker meaning. Utterance meanings belong to a system of default meanings associated with certain expression types. These default meanings are distinct from literally encoded expression meanings. However, when a speaker utters an expression of this type in a normal context, she will have conveyed the default meaning, unless she either explicitly or implicitly cancels this meaning. Levinson identifies these default meanings with the class of conversational implicatures that Grice called generalized conversational implicatures. For instance, when Peter accuses Mary of having eaten all the cookies and Mary replies that she has eaten some of the cookies, she explicitly says that she has eaten some and possibly all of the cookies, she implicates in a generalized way that she has not eaten all of the cookies, and she implicates in a particularized way that she is not the guilty party. These three meanings correspond to Levinson's three levels of sentence, utterance, and speaker meaning, respectively.

The distinction between expression and speaker meaning has been invoked in many philosophical debates as a way of avoiding the postulation of multiple meanings for a single expression type. One well-known instance is Kripke's (1977) appeal to a distinction between speaker's reference and semantic reference of definite descriptions. Kripke appealed to this distinction in order to deny the semantic significance of what Donnellan (1966) called the referential use of such descriptions. Suppose Mary uses the description 'the man in the corner drinking a Martini,' intending to refer to Peter, but in fact Peter is drinking water, not Martini. Kripke argues that the so-called referential use of the description can be accounted for by appeal to what Mary meant to convey by the use of that expression, whereas what she actually said is determined by giving a Russellian analysis of the description. Since there is no unique Martini drinker in the corner (since, let us suppose, there is no Martini drinker there), what Mary has said is false, although what she meant to convey (her speaker meaning) may very well have been true.

There are differing views as to the relative priority of expression and speaker meaning. Some philosophers, such as Strawson (1950), have argued that it is not words and sentences by themselves that refer or express propositions. Rather, it is speakers who refer or express propositions by their uses of words and sentences, respectively. Salmon (2004) calls this the speech-act-centered conception of semantics and contrasts it with the view he favors, namely the expression-centered conception. According to the latter conception, words and sentences have their semantic properties intrinsically, in the sense that one can talk about the referential and truth-conditional content of expressions without any knowledge of or appeal to the communicative intentions of users of those expressions.

Although defenders of the speech-act-centered conception are committed to denying that expressions have referential or truth-conditional content independently of speakers' communicative intentions, their view is compatible with the claim that expression types have aspects of meaning that are context invariant. These would correspond to Fregean 'senses' or 'modes-of-presentation' or (for demonstratives and indexicals) to Kaplanian 'characters.' Such nonreferential or nontruth-conditional aspects of meaning may be intrinsic in Salmon's sense. In other words, such meaning would be a property of expression types, independently of the intentions of the users of those expression types.

Some philosophers of language have denied the idea of intrinsic expression meaning independent of speaker meaning. For instance, Grice (1957) argued that expression meaning is reducible to speaker meaning. Grice was interested in nonnatural meaning ($\text{Meaning}_{\text{NN}}$), as opposed to the sort of natural meaning that a sign may have in virtue of naturally signaling or indicating some state of affairs. He argued that an utterance's nonnaturally meaning that *p* is simply a matter of a speaker's uttering an expression with a certain communicative intention. This would be a sort of 'one-off' meaning for that expression. However, that speaker may be disposed to utter an expression of this type whenever he wishes to convey a certain meaning. Thus, he might develop a habit of using that expression type that way. If this usage were then to spread to other members of his community, it would become a standardized usage, and that expression type would come to have a stable meaning independent of the intentions of any one speaker. But such a meaning would not be independent of the linguistic activities of the users of the expression type in general.

Another way that defenders of a speech-act-centered conception have challenged the idea of intrinsic expression meaning is to argue with Searle (1983) that all meaning is relative to a nonintentional Background. A sentence only has truth-conditions relative to some assumed Background. This Background can never be made fully explicit, because at bottom it consists in a set of abilities, practices, and ways of acting that are nonintentional. Although Searle, unlike Grice, is not suggesting that expression meaning depends ultimately on the communicative intentions of speakers, he is arguing that expression meaning depends on a certain sort of human activity, and so this conception is antithetical to the idea of intrinsic expression meaning.

Expressive Power of Language

D Gil, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany

The expressive power of a language is its ability to convey meanings of various kinds. Most often, the term is used in comparative or contrastive contexts, for example, to claim that one language is of greater expressive power than another in a certain semantic domain.

At one time, it was believed that the classical languages of Western civilization enjoyed much greater expressive power than the so-called primitive languages of Africa, Asia, Oceania, and the Americas. However, when linguists began familiarizing themselves with more distant and exotic languages, it became clear that they were anything but impoverished in their expressive power. Today, it is generally accepted that all languages are endowed with expressive power of similar order of magnitude.

Nevertheless, within particular domains, languages may still vary substantially with respect to their expressive power. Perhaps the most celebrated example of crosslinguistic variation in expressive power, the Eskimos' purported plethora of 'snow words,' has

Some philosophers of language have denied the idea of intrinsic expression meaning independent of speaker meaning. For instance, Grice (1957) argued that expression meaning is reducible to speaker meaning. Grice was interested in nonnatural meaning (Meaning_{NN}), as opposed to the sort of natural meaning that a sign may have in virtue of naturally signaling or indicating some state of affairs. He argued that an utterance's nonnaturally meaning that *p* is simply a matter of a speaker's uttering an expression with a certain communicative intention. This would be a sort of 'one-off' meaning for that expression. However, that speaker may be disposed to utter an expression of this type whenever he wishes to convey a certain meaning. Thus, he might develop a habit of using that expression type that way. If this usage were then to spread to other members of his community, it would become a standardized usage, and that expression type would come to have a stable meaning independent of the intentions of any one speaker. But such a meaning would not be independent of the linguistic activities of the users of the expression type in general.

Another way that defenders of a speech-act-centered conception have challenged the idea of intrinsic expression meaning is to argue with Searle (1983) that all meaning is relative to a nonintentional Background. A sentence only has truth-conditions relative to some assumed Background. This Background can never be made fully explicit, because at bottom it consists in a set of abilities, practices, and ways of acting that are nonintentional. Although Searle, unlike Grice, is not suggesting that expression meaning depends ultimately on the communicative intentions of speakers, he is arguing that expression meaning depends on a certain sort of human activity, and so this conception is antithetical to the idea of intrinsic expression meaning.

Expressive Power of Language

D Gil, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

The expressive power of a language is its ability to convey meanings of various kinds. Most often, the term is used in comparative or contrastive contexts, for example, to claim that one language is of greater expressive power than another in a certain semantic domain.

At one time, it was believed that the classical languages of Western civilization enjoyed much greater expressive power than the so-called primitive languages of Africa, Asia, Oceania, and the Americas. However, when linguists began familiarizing themselves with more distant and exotic languages, it became clear that they were anything but impoverished in their expressive power. Today, it is generally accepted that all languages are endowed with expressive power of similar order of magnitude.

Nevertheless, within particular domains, languages may still vary substantially with respect to their expressive power. Perhaps the most celebrated example of crosslinguistic variation in expressive power, the Eskimos' purported plethora of 'snow words,' has

recently been called into question; however, numerous other examples are empirically well-supported. In order to compare the expressive power of languages, it is necessary to consider the forms that may bear meanings, the meanings that may be borne by those forms, and the nature of the form-meaning relationship.

The forms that may bear meanings are linguistic units of various size: morphemes, words, phrases, clauses, sentences, and texts. Alongside these, intonation contours may also be associated with meanings. In addition, smaller, phonological units may bear meanings in what is known as sound-symbolism.

The meanings that are borne by linguistic forms may be broadly characterized as either conceptual or affective. Conceptual meanings are based on the traditional notions of semantics, such as propositional content, modality, and reference, and may be further classified into various semantic domains, including thematic roles, tense/aspect, quantification, kinship terms, color terms, weather terms, and so forth. In contrast, affective meanings involve states such as tension, happiness, arousal, and their like.

The form-meaning relationship, that is to say the association of linguistic forms with their particular meanings, is the basis of the expressive power of language. For any given meaning M, the following three cases may, potentially, be distinguished: (a) M is expressible in all languages; (b) M is expressible in no languages; and (c) M is expressible in some but not all languages. However, the above taxonomy faces a number of serious problems.

One difficulty is empirical: without access to each and every one of the world's thousands of languages, it is an extremely risky proposition to make any universal generalizations to the effect that a certain meaning may be expressible in all languages, or in none. In lieu of a much larger data base than is currently available, all such claims must therefore be treated as conjectures of various degrees of plausibility.

Another issue pertains specifically to the meanings purportedly expressible in no languages. Some scholars view language as system of societal conventions, and meanings, in particular, as essentially public entities: for such scholars, the concept of an unexpressible meaning is therefore an oxymoron. More generally, by their very definition, meanings expressible in no language can never be referred to, even indirectly, as in expressions such as *the meaning of Mona Lisa's smile*: the very notion of unexpressible meaning is thus paradoxical.

Nevertheless, prophets, poets, and others have reported undergoing mystical experiences beyond the realm of linguistic expression; similar claims are also made by persons who have entered altered states of consciousness, for example, with hallucinogenic drugs. Indeed, the logical positivists maintained that natural languages are incapable of expressing scientific concepts with sufficient precision; this postulate was their motivation for proposing an 'artificial language of science.' More far reachingly, cognitive scientists have suggested that the human mind is innately incapable of grasping certain kinds of knowledge; such knowledge would, *a fortiori*, be unexpressible in any language. In view of such claims, it would therefore seem advisable to at least entertain the possibility that there may exist meanings expressible in no languages, in spite of the problems inherent therein.

A further, much-debated issue is that of crosslinguistic synonymy. Some linguists question whether linguistic forms in different languages are ever capable of bearing the exact same meaning. Each and every linguistic form is part of a language system; hence, it is argued, linguistic forms belonging to different language systems can never be equivalent. The issue of crosslinguistic synonymy is of course crucial to the process of translation: if complete crosslinguistic synonymy is not attainable, neither is the 'perfect translation.' Nevertheless, for many purposes, it would seem advantageous to abstract away from such subtleties, in order to posit crosslinguistic synonymy, when equivalence of meaning, up to a certain point, can be seen to obtain.

A particular problem arises when supposed crosslinguistic synonyms are constructed from linguistic forms of different types, or 'sizes.' Consider, for example, the English expression *boy* and its nearest equivalents in Hebrew, *yeled*, and in Tagalog, *batang lalaki*. Whereas English has a monomorphemic word, Hebrew possesses a bimorphemic word consisting of root *y-l-d* 'child' plus masculine singular inflection *-e-e-*, while Tagalog makes use of two words, *batang* 'child' plus a grammatical linker, and *lalaki* 'male.' It is at least plausible to suggest that the meanings associated with *boy*, *yeled*, and *batang lalaki* reflect their different structures. Specifically, whereas a semantic representation of *boy* might involve a primitive concept Boy, that of *yeled* might be obtained by application of a masculine feature to Child, while that of *batang lalaki* might be constructed compositionally, by modifying Child with Male.

It would therefore seem crucial to distinguish between the different types of linguistic forms that may bear meanings: segments, morphemes, words, phrases, clauses, sentences, texts, intonation contours, and so forth. Specifically, for any meaning M, and any type of linguistic form T, the following three cases may be distinguished: (a) M is expressible by a

form of type T in all languages; (b) M is expressible by a form of type T in no languages; and (c) M is expressible by a form of type T in some but not all languages. Following are some examples of each of these three cases.

Taking T to be morpheme, and examining the semantic domain of cardinal numerals, One is possibly expressible by a single morpheme in all languages, whereas One Hundred And Twenty Three is almost certainly expressible by a single morpheme in no languages. In between these two extremes, Eleven is expressible by a single morpheme in English *eleven*, but not in Malay, where *seblas* consists of *se-* 'one' plus *-blas* 'over ten'; while One Hundred Thousand is expressible by a single morpheme in Hindi *laakh*, but not in English.

Letting T stand for word and generalizing the semantic domain to that of quantification, One is possibly expressible by a single word in all languages, whereas At Most Four Or More Than Seven is almost certainly expressible by a single word in no languages. In between, the quantifier No is expressible by a single word in English *no* (as in *no languages*), but not in Hebrew, where it would be paraphrased with a negative polarity marker *af* preceding the noun plus a negation *lo* in construction with the verb; while Only One is expressible by a single word in Tagalog *iisa,* but not in English.

Taking T to denote clause, simple propositions such as John Came are perhaps expressible by a single clause in all languages, whereas a conditional linking two events such as If John Comes, Bill Will Go most probably cannot be expressed monoclausally in any language. However, propositions involving conjoined participants such as John And Bill Came can be expressed by a single clause in English, *John and Bill came*, but not in the Amerindian Yuman language Maricopa, where its nearest equivalent, *John-ʃ Bill uðaavk vʔaawk*, contains an embedded clause *John-ʃ Bill uðaavk* 'John accompanied Bill.' Conversely, propositions involving indirect causation such as John Caused Bill To Write A Letter can be expressed monoclausally in Hindi, as in *John-ne Bill-se khat likhwaayaa*, making use of a single verb *likhwaayaa* 'write' inflected for indirect causation, but not in English, where, in the nearest equivalent, *John caused Bill to write a letter*, two verbs, *caused* and *write,* head two different clauses.

Letting T represent intonation contour, emphasis is probably expressible via intonation in all languages, while a cardinal numeral such as Seven is almost certainly expressible through intonation in no languages. However, yes/no questions can be formed with intonation in English, but not, allegedly, in Thai, whereas 'a variety of exclamation colorings,' including 'the lack of concern on the part of the speaker for the outcome of his utterance' can be expressed intonationally in Vietnamese, but not in English.

Finally, taking T to denote phonological feature, harshness and aggression are possibly expressible, through sound symbolism, by the feature [obstruent] in all languages, while a cardinal numeral such as Seven is almost certainly expressible with a phonological feature in no languages. However, since the association of phonological features with meanings is based on universal cognitive principles, falling outside the domain of conventionalized and possibly language-specific grammatical rules, there are probably no cases of meanings expressible by phonological features in some but not all languages.

In those cases where a meaning M is expressible by a form of type T in some but not all languages, the availability of M as a meaning of a Type T form may be correlated with various other linguistic properties. Such correlations can be represented as implicational universals of the following form: (a) For any language L, if M is available as a meaning of a Type T form in L, then L has property P; and (b) For any language L, if L has property P, then M is available as a meaning of a Type T form in L. At present, however, not enough is known about patterns of crosslinguistic variation in expressive power to conclusively support a significant body of such universals. Nevertheless, some work in linguistic typology has pointed towards possible correlations between expressive power and various other linguistic properties.

For example, in phonological typology, it has been suggested that intonation is associated with less expressive power in tonal languages than in their nontonal counterparts. Similarly, in morphological typology, the word is generally endowed with less expressive power in isolating languages than in synthetic ones, and less expressive power in synthetic languages than in polysynthetic ones, such as the Australian language Mayali, in which a single word *gayauganjngunihmiwage* can mean 'the child crawls along eating meat.' Analogously, in syntactic typology, the sentence is generally equipped with less expressive power in English and other European languages than in several Papuan languages of the so-called clause chaining type, in which a single sentence can narrate a series of events that, in most other languages, would require a lengthy sequence of sentences.

While some facts and generalizations about the expressive power of language can be accounted for terms of linguistic typology, others would seem to result from extralinguistic factors, while yet others would appear to be immune to either kind

of explanation, instead reflecting the arbitrariness of language and linguistic structure.

Extensionality and Intensionality

N Oldager, Technical University of Denmark, Lyngby, Denmark

© 2006 Elsevier Ltd. All rights reserved.

A sentence is extensional if its expressions can be substituted with expressions that have the same denotation (reference) without altering the truth value of the sentence. A sentence that is not extensional is intensional. A language is extensional if every sentence of it is extensional. Otherwise, the language is intensional.

The following sentence is then intensional:

George IV wished to know whether Scott was the author of *Waverly*.

As Scott was in fact the author of *Waverly*, 'Scott' and 'the author of *Waverly*' are co-denotational. However, if we substitute one for the other, we get

George IV wished to know whether Scott was Scott,

which, unlike the former, can hardly be taken as true. Because natural language contains intensional sentences, natural language is intensional.

A context in which co-denotational expressions cannot be substituted is known as an indirect context (or oblique, opaque or intensional context), and a context of extensional expressions is a direct context. Sentences involving propositional attitudes, intentions, quotations, temporal designation, and modalities give rise to indirect contexts. Another example of intensionality:

Nine necessarily exceeds seven.
Nine is the number of the planets.
The number of the planets necessarily exceeds seven.

Although the first two sentences are true, the third is not because it is only a contingent astronomical fact and not a necessary truth that the number of planets exceeds seven – it is possible that there were only seven planets.

Semantical Aspects of Extensionality and Intensionality

Issues concerned with extensionality and intensionality have been cardinal motivations behind the development of important semantical theories. Reducing extensionality and intensionality to technical conditions regarding substitutivity of expressions is accordingly a crude simplification.

Though extensionality and intensionality can be traced as far back as ancient Greek philosophy, the first major contribution to the subject was Gottlob Frege's *Über Sinn und Bedeutung* (Frege, 1892). Note, there are different translations of the title words of this work: *Sinn* is translated as 'sense' but *Bedeutung* is translated as either 'denotation', 'reference', or 'nominatum' ('meaning' has actually been used for both *Sinn* and *Bedeutung*). Following Bertrand Russell and Alonzo Church, *Bedeutung* will be identified with 'denotation'.

Although Frege does not spell it out in detail, he maintains that semantics is compositional, such that the semantics of a sentence is determined by the semantics of its parts. To illustrate his theory, assume, to begin with, that semantics is purely referential, that is, assume that the semantics of an expression is what

of explanation, instead reflecting the arbitrariness of language and linguistic structure.

A sentence is extensional if its expressions can be substituted with expressions that have the same denotation (reference) without altering the truth value of the sentence. A sentence that is not extensional is intensional. A language is extensional if every sentence of it is extensional. Otherwise, the language is intensional.

The following sentence is then intensional:

George IV wished to know whether Scott was the author of *Waverly*.

As Scott was in fact the author of *Waverly*, 'Scott' and 'the author of *Waverly*' are co-denotational. However, if we substitute one for the other, we get

George IV wished to know whether Scott was Scott,

which, unlike the former, can hardly be taken as true. Because natural language contains intensional sentences, natural language is intensional.

A context in which co-denotational expressions cannot be substituted is known as an indirect context (or oblique, opaque or intensional context), and a context of extensional expressions is a direct context. Sentences involving propositional attitudes, intentions, quotations, temporal designation, and modalities give rise to indirect contexts. Another example of intensionality:

Nine necessarily exceeds seven.
Nine is the number of the planets.
The number of the planets necessarily exceeds seven.

Although the first two sentences are true, the third is not because it is only a contingent astronomical fact and not a necessary truth that the number of planets exceeds seven – it is possible that there were only seven planets.

Semantical Aspects of Extensionality and Intensionality

Issues concerned with extensionality and intensionality have been cardinal motivations behind the development of important semantical theories. Reducing extensionality and intensionality to technical conditions regarding substitutivity of expressions is accordingly a crude simplification.

Though extensionality and intensionality can be traced as far back as ancient Greek philosophy, the first major contribution to the subject was Gottlob Frege's *Über Sinn und Bedeutung* (Frege, 1892). Note, there are different translations of the title words of this work: *Sinn* is translated as 'sense' but *Bedeutung* is translated as either 'denotation', 'reference', or 'nominatum' ('meaning' has actually been used for both *Sinn* and *Bedeutung*). Following Bertrand Russell and Alonzo Church, *Bedeutung* will be identified with 'denotation'.

Although Frege does not spell it out in detail, he maintains that semantics is compositional, such that the semantics of a sentence is determined by the semantics of its parts. To illustrate his theory, assume, to begin with, that semantics is purely referential, that is, assume that the semantics of an expression is what

the expression denotes. This seems plausible; for example,

Paris is beautiful

asserts that what 'Paris' denotes, i.e., the actual capital of France, has the property of being beautiful. It is not the string of symbols 'Paris' or one's idea of Paris, whatever that may be, which is beautiful.

However, things are more complicated than this. There are aspects of natural language semantics that cannot be explained by resorting to the notion of denotation, Frege argues. He illustrates this by the following puzzle. Suppose a and b are names for some objects and that

$$a = b$$

is true, hence the expressions 'a' and 'b' have the same denotation.

Frege then recognizes a difference between this identity and an identity such as $a = a$. The latter is trivially true (analytically true), whereas the former may contain useful information. For instance, in a criminal investigation a discovery such as "the burglar is the suspect" could be decisive, whereas "the burglar is the burglar" is useless. The important question is then: What is the source of the difference between $a = a$ and $a = b$? As semantics is compositional, the difference must be due to a difference between the semantics of the expressions 'a' and 'b'. But by assumption, 'a' and 'b' have the same semantics because they have the same denotation. In other words, referential semantics must be rejected because it cannot explain the difference between the identities.

Frege's famous solution is to acknowledge that 'a' and 'b' refer to their denotation in different ways. Consider, for example, the expressions 'morning star' and 'evening star.' Both denote the planet Venus, so *morning star = evening star* is true, but they refer to Venus in different ways: One refers to a heavenly object seen in the morning, the other to a heavenly object seen in the evening. Frege says 'morning star' and 'evening star' have different senses. The puzzle about identity can now be solved by noting that $a = a$ and $a = b$ express different senses. Frege was inspired by mathematics when he developed this theory. Consider the two expressions '$1 + 3$' and '$2 * 2$'. Both are equal to, i.e., denote, the number 4, however, their way of referring to four differs because the calculations for obtaining the result differ. Hence, the expressions have different senses.

To solve the puzzle, Frege accordingly introduces two semantical concepts, denotation and sense. Each expression – including proper names and sentences – is then assumed to have both a denotation as well as a sense, although he recognizes that exceptions may occur. Frege never precisely described what senses are, but he explained that the sense of an expression contains its mode of presentation (its way of referring), that expressions express their senses, and senses are something we grasp. Moreover, senses are distinguished from ideas (subjective thinking), meaning they are objective. The notion of sense may appear unfamiliar and it may not be clear why it is seminal. However, expressions such as 'morning star' or 'Paris' are signs, and signs are characterized by their ability to refer to something. Sense addresses this fundamental feature – the referential capacity of expressions. So, it is natural to discern between expressions that refer to the same thing.

There is a close relationship between Frege's theory and the earlier definition of extensionality and intensionality. Frege can now provide an explanation for failure of substitutivity in indirect contexts. In indirect contexts we are talking about the senses of the expressions occurring therein. When we say

John believes that the morning star is the evening star

we are not talking about Venus, Frege argues, but about different senses that determine Venus. In indirect contexts the semantics become the sense. Thus, when we substitute two co-denotational expressions that have different senses in indirect contexts, we obtain different propositions that may have different truth values.

Frege's theory has been challenged by, among others, Bertrand Russell (Russell, 1905). Russell notes that in Frege's theory, a phrase such as "the present Queen of England" denotes an actual woman. It would seem, by parity of form, that a phrase like "the present King of France" also is about, i.e., denotes, an actual individual. However, as an actual King of France does not exist, this sentence does not denote – it merely expresses a sense. Only when sentences are false or nonsense, do we talk about senses, it seems. Russell then presents a rival theory of denotation which, by means of a clever paraphrasing technique, does not resort to Fregean senses. However, it faces other difficulties. For instance, Russell would have to accept that

Ponce de Leon sought the fountain of youth

is either false or nonsense because there did not exist an actual fountain of youth.

There are other semantical theories and notions similar to Frege's. The notion of connotation is similar to sense. Rudolf Carnap (Carnap, 1947) has presented a semantical method in which he distinguishes the notions extension and intension. These are closely

related to Frege's notions, in fact, in direct contexts extension and denotation are the same, and so are intension and sense; only in indirect contexts does Carnap distinguish his notions from Frege's. Common to these theories is the distinction between two semantical notions, one more general than the other.

Extensionality and Intensionality in Formal Settings

So far, the investigations have been restricted to natural language; in the following they will be generalized to logic. The underlying idea is to formalize the condition for extensionality (substitutivity of co-denotational expressions). This will allow us to determine whether a logic is extensional or intensional.

In propositional logic, the formula

(1) $(P \leftrightarrow Q) \rightarrow (R \leftrightarrow R[Q/P])$

is valid (logically true) for all formulas P, Q, and R, where R[Q/P] is the result of substituting zero or more occurrences of P with Q in R. This result says that equivalent (co-denotational) formulas can be substituted with preservation of truth, hence, that propositional logic is extensional.

In contrast, modal logic is intensional because (1) is not valid in modal logic. We have the following counterexample comprising the necessity operator:

$$(p \leftrightarrow q) \rightarrow (\Box\, p \leftrightarrow \Box\, p[q/p]),$$

that is,

$$(p \leftrightarrow q) \rightarrow (\Box\, p \leftrightarrow \Box\, q)$$

is not valid, where p and q are atomic propositions. Thus, in modal logic we cannot substitute equivalent formulas, but this is precisely what we want because modal logic formalizes the intensional notion of modality. The example shows that $\Box$ creates an indirect context.

Presenting a general, formal definition of when a logic is extensional is no trivial task. One reason is that the notion of logic is general indeed, meaning there are several, non-equivalent formalizations of the condition for extensionality. Consider first-order predicate logic, which is commonly said to be extensional. If we accept open formulas (formulas in which variable occurrences are not bound, such as $F(x)$), formula (1) is not valid. But this means that we would have to say that predicate logic is intensional. However, (1) is not the only formalization of the condition for extensionality for predicate logic. As an alternative formalization, we have:

(2) If $P \leftrightarrow Q$ is valid then $R \leftrightarrow R[Q/P]$ is valid.

The difference between this formalization and (1) is that (2) is formulated in metalanguage. As (2) holds, it says that predicate logic is extensional in terms of metalogical formalization. Unfortunately, we cannot adopt (2) as a general formalization of extensionality because modal logic also satisfies (2), meaning it would become extensional too. A possible solution is to discard open formulas in predicate logic and accept (1) as a formalization of extensionality. However, other solutions might be preferred. It has been suggested, e.g., by Ruth Barcan Marcus (Marcus, 1960), that there are several principles (definitions) of extensionality, and hence also several principles of intensionality. This reveals subtleties in the distinction between extensionality and intensionality.

Because of their imprecise nature, intensional notions such as sense have been deemed opaque. However, the last 50 years of developments in non-classical logic, in particular the development of possible-world semantics by such people as Saul Kripke and Richard Montague (1970), have shown that a significant part of intensional notions can be formulated in precise (mathematical) settings. See Gamut (Gamut, 1991) for an introduction and Fitting and Mendelsohn (Fitting and Mendelsohn, 1998) for newer developments in possible-world semantics.

Externalism about Content

J Brown, Bristol University, Bristol, UK

© 2006 Elsevier Ltd. All rights reserved.

The Thesis of Externalism

Externalism is a thesis in the philosophy of mind about thought content, i.e., what is believed, desired, hoped, feared, etc. We can distinguish externalism and its opposite, internalism, by contrasting relational properties such as the property of being taller than the Eiffel Tower, and intrinsic properties, such as the property of being made of iron. Externalism treats the property of having a certain thought content as a relational property, whereas internalism treats it as an intrinsic property.

As an example, let Oscar and Twin Oscar share all their intrinsic properties: they are molecule-for-molecule physical duplicates; they share all the same dispositions to behave, where behavior is construed as bodily movement non-intentionally described; and they share all the same 'narrow' functional properties, i.e., functional properties defined in terms of causal relations within the body. Externalism claims that Oscar and Twin Oscar may have different thought contents if they are in different environments. Internalism claims that Oscar and Twin Oscar have the same thought contents. Thus we may understand the dispute between externalism and internalism in terms of supervenience. Internalism claims, while externalism denies, that thought content supervenes on the properties that duplicates like Oscar and Twin Oscar share.

Externalism has important consequences for the philosophical debate about the relation of mind and body. Externalism is incompatible with the behaviorist claim that talk of mental states can be reduced to talk of dispositions to behave, where behavior is construed as bodily movement non-intentionally described. Further, externalism is incompatible with the reduction of types of mental state either to types of brain state, or to narrow functional types. Externalism rejects the Cartesian supposition that a normally embodied person and an always envatted brain (i.e., one not connected to a real body in a real world) could have all the same mental states while being in radically different environments. (Notice that externalism and internalism should not be understood as disputing the uncontroversial truth that a subject's environment causally affects what she thinks. For instance, an internalist who claims that types of mental state are identical to types of brain state may agree that a subject's environment causally affects what types of brain state he is in, and so what types of mental state he is in.)

Arguments for and against Externalism

Natural Kind Terms

Putnam's classic twin earth argument for externalism asks us to imagine that there is a far away planet, Twin Earth, that is a physical duplicate of Earth and that contains duplicates of all Earthians. The only difference between the planets is that whereas, on Earth, the stuff that flows in rivers and falls as rain has chemical composition H_2O, on Twin Earth, the stuff that flows in rivers and falls as rain is an identical seeming stuff that has a different chemical composition, abbreviated XYZ. Consider an Earthian, Oscar, in 1750 when the chemical composition of water was not yet known. Putnam claims that when Oscar sincerely says, "Water is wet," the term 'water' and the concept it expresses refers to all and only H_2O, so that the truth value of Oscar's utterance and thought turns on the properties of H_2O. By contrast, Putnam claims that when Oscar's Twin Earthian twin, Twin Oscar, makes the same utterance, the term 'water' and the concept it expresses refers to all and only XYZ, so that the truth value of Twin Oscar's utterance and thought turns on the properties of XYZ. Given that it's an assumption of the thought experiment that Oscar and Twin Oscar are physical duplicates, the fact that their utterances and thoughts are about different substances and have different truth conditions seems to support the externalist claim that a subject's thought contents are partly individuated by the sorts of substances present in his environment.

As initially set-up, the thought experiment suffers from the fact that since humans are largely made out of water, Oscar and Twin Oscar cannot be physical duplicates. However, the thought experiment can easily be reformulated to overcome this objection, by using a term for a 'natural kind' that is not part of the physical constitution of humans. The thought experiment exploits the idea that we intend some of our terms to refer to natural kinds that are naturally demarcated by their fundamental properties, and it is the job of science to discover those properties. On this view, an item could appear superficially just like instances of a certain natural kind and yet not be of that natural kind if it lacks the relevant fundamental properties (e.g., fool's gold). Further, an item could be of a certain natural kind even without possessing its characteristic appearance if it has the fundamental

properties definitive of that kind (e.g., an albino tiger). If we intend 'water' to refer to such a natural kind, then XYZ is not included in the reference of our term for, although it looks and behaves like H_2O, XYZ is stipulated to differ in its fundamental chemistry.

One could object to Putnam's Twin Earth argument by rejecting some of the assumptions on which it lies: for example, that there are natural kinds, that some of our non-technical terms aim to refer to such kinds, and that if a substance like XYZ were discovered it would be incorrect to regard it as of the same natural kind as H_2O. Even if all these assumptions are granted, one could further object to the argument that one can accommodate the idea that Oscar's and Twin Oscar's thoughts refer to different substances without granting the externalist claim that their thought contents are partly individuated by the substances in their respective environments. Suppose that each would explicate the meaning of 'water' as "the watery stuff around here." On this explication, since the watery stuff in Oscar's environment is H_2O, in his mouth, 'water' would refer to H_2O. By contrast, since the watery stuff in Twin Oscar's environment is XYZ, 'water' in Twin Oscar's mouth would refer to XYZ. In this way, someone could hope to explain how Oscar's and Twin Oscar's utterances and thoughts refer to different substances within a view that treats their reference as being determined by a common rule, or 'character' in Kaplan's sense. Such a 'two-dimensionalist' view could arguably be used to support an internalist account of Putnam's Twin Earth story.

Indexicals

A second argument for externalism concerns reference to particular objects, rather than natural kinds. Suppose that a subject sees a blue lamp and says, "That lamp is broken." His utterance and the thought it expresses refer to the lamp he sees, and their truth value turns on the properties of that object. An internalist could suggest that the content of the demonstrative expression and the corresponding thought constituent is given by a certain condition such that the demonstrative expression and thought constituent refer to an object if and only if it meets that condition, say the condition of being the unique blue lamp (on some interpretations, this condition is an example of a Fregean 'sense'). On this view, in a counterfactual condition in which the subject is in the same intrinsic state but looking at a duplicate lamp he would have the same thought content. However, there are a number of objections to the suggested internalist understanding of demonstrative reference. First, it is hard to specify a condition that both uniquely picks out the intuitive referent and that is plausibly available to any subject capable of making or understanding demonstrative reference. Second, understanding the demonstrative expression arguably only requires latching onto the right object, regardless of how one conceives of it. As a result of these difficulties, externalists suggest that the object referred to partly specifies the content of the demonstrative expression and thought constituent, so that if the subject had instead been looking at a duplicate lamp the content of his thought and utterance would have been different. This alternative view supports the externalist claim that a subject's thoughts are partly individuated by the objects in his environment. An internalist could try to avoid this conclusion by exploiting a two-dimensionalist framework in a way analogous to the potential two-dimensionalist reply to Putnam's argument.

Burge and Linguistic Practice

A third argument for externalism, forwarded by Burge, aims to show that a subject's thought contents are partly individuated by the linguistic practices of his community. Burge's argument concerns a subject, Alf, an ordinary member of the English-speaking community and arthritis sufferer who complains to his doctor, "I fear my arthritis has spread to my thigh." This attitude indicates that Alf incompletely understands arthritis for, by definition, 'arthritis' applies only to problems of the joints. Despite this, Burge argues that Alf has the concept arthritis and that, by his utterance, he expresses the fear that his arthritis has spread to his thigh. Burge supports this interpretation by saying that it would be natural to report Alf's thoughts in this way, despite his incomplete understanding.

Now consider a duplicate of Alf, Twin Alf, who has been brought up in a counterfactual linguistic community in which 'arthritis' is instead defined to apply to rheumatoid ailments of the joints and thighs. In the counterfactual situation, the term 'arthritis' does not express the English concept arthritis. Like Alf, Twin Alf complains to his doctor, "I fear that my arthritis has spread to my thigh." Burge argues that, in the counterfactual situation, Twin Alf lacks the concept arthritis and thus expresses a different thought by his utterance than Alf does. This claim is supported both by the way Twin Alf would explicate 'arthritis' and by how experts in his community would explicate the term. Unlike Putnam's Twin Earth argument, Burge's argument can use a variety of terms and needn't use natural kind terms.

Burge's argument relies on the idea that one may have a concept that one incompletely understands. So, an internalist might object to Burge's argument by rejecting this assumption. In reply, an externalist

may point out that the notion that a subject may incompletely understand a concept she possesses is supported by our ordinary practice of attitude ascription in which we routinely ascribe concepts to subjects even despite their incomplete understanding of the relevant term, and regard them as sharing beliefs with others who fully understand the term. Further, it seems supported by Alf's own understanding of the situation. Suppose that the doctor reassures Alf, saying that, by definition, arthritis cannot occur in thighs. It seems likely that Alf would defer to the doctor about the application of 'arthritis,' and regard his earlier fear as false. But, this response suggests that it is the public concept arthritis that figures in his belief, not some idiosyncratic concept defined by his own views.

Accounts of Content

As well as the particular arguments for externalism detailed above, a more general motivation arises from "naturalistic accounts of content." Such accounts start from the thought that content is not a fundamental feature of the world but can be accounted for in terms of other non-intentional features of the world. On the "causal account," what it is for a state of a system to have a certain content is for it to bear certain kinds of causal relations to other items. On the "teleofunctional account," a state of a system has a certain content if and only if it has a certain evolutionary history. On both of these leading naturalistic accounts, what it is for a state of a system to have a certain content involves its relational properties to items outside that system.

Externalism's Consequences

In addition to its consequences for the mind-body debate (detailed above), externalism has been claimed to have controversial consequences in epistemology and philosophy of mind, in particular for knowledge of one's own mind, knowledge of the world, and the explanation of action. If one's thoughts are partly individuated by the environment, it seems hard for one to know what one thinks just by introspection and without first investigating the environment. Further, if what one thinks depends on the kind of environment one is in, then it may seem that were one to know what one thinks introspectively one could use that knowledge to gain knowledge of the environment without first investigating it! Externalism may also seem to conflict with the plausible intuition that what one thinks causally explains one's actions, given the metaphysical assumption that causal powers depend on intrinsic and not relational properties.

Face

F Bargiela-Chiappini, Nottingham Trent University, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Background

A search for 'face' in the on-line *Oxford English dictionary* (OED) yields pages on this polysemic entry. It also illuminates the cultural and psychological dimensions of the construct that lies at the heart of a well-known model of linguistic politeness expounded by Brown and Levinson in their seminal work *Politeness: some universals in language usage* (1978, 1987) (*see* **Politeness**). The Western character of their (positive and negative) face derives from an Anglo-Saxon understanding of the rational individual who seeks to protect himself or herself, and others, from Face-Threatening Acts (FTAs). In spite of its claim to universality, the politeness model that stems from this characterization of face is also, inevitably, culture-biased (*see* **Intercultural Pragmatics and Communication**).

In reaction to this, a critical reappraisal of Brown and Levinson's notion of face has engaged scholars beyond the Anglophone world, who have brought to their analyses insights from psychology, philosophy, and anthropology. In particular, critique from Asian linguists has now grown into a consistent contrastive body of research, which has expanded to include perspectives from Southern Europe (e.g., Turkey, Greece, Spain, Italy), South America (e.g., Ecuador, Argentina), and South Africa, thus widening considerably the cultural spread of the debate.

If it is thanks to two British anthropologists (Brown and Levinson) that linguistic politeness rose to become the subject of ongoing scholarly debate, it is too easily forgotten that it was an American sociologist who gave us the powerful account of 'face' that stands at the heart of it. Not a universal account, however; in fact, Erving Goffman's 'face' is American in many of its facets, and yet an original contribution to the modern study of the social and psychological relevance of this arguably universal construct to politeness research and human interaction (*see* **Goffman, Erving (1922–1982)**).

Face as a philosophical construct boasts a history that dates to ancient civilizations. For example, the Náhuatl people who inhabited Central America would use the expression 'face-heart' (Spanish *rostro-corazón*) to define personhood. In their understanding, "face seems to refer to the physiognomy of the self while the heart is the dynamic aspect of self" (Jiménez Cataño, 1993: 72) (my translation). In modern times, among the more defining influences on Goffman's early work and his conceptualization of face are Chinese and American Indian sources and the work of the French sociologist Émile Durkheim (*see* **Durkheim, Emile (1858–1917)**).

'Face' According to Goffman

Even though Goffman was primarily concerned with uncovering the rules governing social interaction, his treatment of 'face' leads the reader to believe that he saw it as the hub of interpersonal dynamics; in fact, for Goffman 'face-saving' was shorthand for 'the traffic rules of social interactions' (1967:12). His concept of face, unlike Brown and Levinson's later understanding of it, seeks to accommodate both strategic and social indexing behaviors and is best apprehended in the context of social order as ritual. Equilibrium is maintained by interactants making choices informed by moral rules. In turn, the social morality underpinning Goffman's order consists of values such as pride, honor, dignity, consideration, tact and poise, perceptiveness and feelings, all of which the self expresses through face. Within the wider social order, face maintenance is a condition rather than the objective of interaction.

Émile Durkheim, the French thinker, saw social action as symbolic ritual enacted through positive and negative rites, hence Goffman's definition of the person as a "ritual object," a "deity," and "his own priest" (1967: 55). However, Durkheim also envisaged solidarity as the glue of the social order. Solidarity between actors would aim for the

fulfillment of obligations toward others as a condition for the maintenance of equilibrium. Goffman's interactant is certainly more individualistic, but avoids the egocentrism of Brown and Levinson's idealized agent. Ultimately, for Goffman as for Durkheim, organizational order comes before the safeguard of the individual self, which can be asked to sacrifice his or her face (with the ensuing embarrassment) for the gain of society (1967: 112).

In 1944, the *American Anthropologist* published Hsien Chin Hu's seminal account of the Chinese concept of 'face.' A decade later, Goffman acknowledged his debt to Hu in his discussion of a Western version of 'face.' Goffman's social psychological definition of face is that of 'the positive social value a person effectively claims for himself by the line others assume he has taken during a particular contact' where a "line" is the interactants' self and others' evaluation (1967: 23). Self-respect and considerateness are safeguards for one's own and others' face in social encounters. These social values underline the interdependent character of Goffman's actor whose face he considers sacred (1967: 19). Face maintenance requires a ritual order, that is 'acts through whose symbolic component the actor shows how worthy he is of respect or how worthy he feels others are of it' (Goffman, 1967: 19). For Goffman, the contemporary and still enduring Anglo-Saxon values of independence and privacy have swung the balance from a Durkheimian collective self to a self-aware, more individualistic self.

Goffman's 'face-work' consists of defensive (saving one's own face) and protective (saving others' face) practices exercised simultaneously, another indication of the social value that he attached to face. "Avoidance" rituals, "corrective" processes, and the "aggressive use of face-work" are also discussed by Goffman in some detail alongside the tacit cooperation that makes face-work possible. Brown and Levinson's model seems to have given preeminence to the first three practices, thus emphasizing the self-defensive, negative posture of their ideal agent.

For Goffman, "tact," "reciprocal self-denial," and "negative bargaining" (favoring one's counterpart) signal the degree of social awareness and concern for others, possibly motivated by self-preservation, which interactants would display as a "ritually delicate object" (1967: 31). In spite of later developments in politeness research that somewhat obscured the originality of Goffman's face, his notion remains a primary object of interest for scholars engaged in the situated study of interpersonal behavior in general and of 'polite behavior' in particular.

Brown and Levinson's 'Face' and Its Critics

Brown and Levinson's positive and negative face is a cognitive, abstract, culture-dependent construct attributable to a rational agent; it makes extensive use of Durkheim's negative (avoidance) rituals. The dualistic notion of face and the emphasis on negative face and the notion of 'imposition' have attracted extensive criticism in subsequent Chinese and Japanese studies of politeness, as well as among other non Anglo-American scholars. Although Brown and Levinson acknowledge Durkheim as their source for negative and positive rites, their understanding of the sociologist's original concepts is substantively altered in their model; their ideal rational actor is busy protecting own and others' face, rather than giving, enhancing, or maintaining face. Emotions, when accounted for, are also means of face-protection.

Such a reductionist perspective has progressively laid bare the need for a sociopsychological and affective construct of face that resonates again with Goffman's original motivation for the study of interaction as being "not about the individual and his psychology, but rather the syntactical relations among the acts of *different persons mutually present to one another*" (1967: 2) (italics added).

It is Brown and Levinson's negative face (and negative politeness) that have been singled out for intensive scrutiny on grounds of cultural relativity. Further, their outline of positive and negative face as mutually exclusive in interaction has been challenged by empirical research that indicates, instead, the coexistence of many face wants calling on simultaneous positive and negative face-work. Similarly, the assumptions that only one type of face can be threatened at any given time and that Face Threatening Acts (FTAs) can be analyzed out of context are highly problematic.

The crosscultural validity of Brown and Levinson's model has buckled under the criticism of suffering from British 'cultural bias' (Baxter, 1984). Research in linguistic politeness in the 1990s indicated a split between cultures where face is a key explanatory construct in interpersonal behavior and those where other values such as discernment, deference, and respect play a more important role. Face and face-work will operate differently in socially stratified cultures (e.g. Japan and Mexico, where normative politeness is dominant) compared to status-based cultures (such as China and Korea), where normative and strategic (volitional) politeness coexist. Where status is allegedly less marked in interpersonal interaction and normative politeness is less in evidence (e.g., Northern

Europe and North America), the concern for face remains nevertheless relevant, even if expressed in a more understated way.

The consolidation of psychology research on the social self and social identity has opened up new contexts of relevance for the dynamics of face and face-work, calling on a modified model of face and politeness that breaks free from the straitjacket of cognitivist psychology. Another exciting development is the emergence of indigenous psychologies from Asia and Africa which, instead of testing Western formulations, may develop their own analytical models and constructs to make true crosscultural comparison possible.

Future of Face Research

For all the criticism of ethnocentrism that their model has generated, Brown and Levinson's work can boast an unmatched and continuing level of interest within the field of linguistic politeness research. Twenty years on, new insights from social and cultural psychology point in the direction of a culture-situated, dynamic understanding of face that gives consideration to other factors such as personal values, one's own self-concept, self-identity in various groupings, role expectations, and normative constraints (Earley, 1997: 95–97). After years of established disciplinary research in politeness, especially in anthropology and linguistics, face is becoming a privileged topic for interdisciplinary research. In addition, its cultural sensitivity calls for more international collaborative research if its sociocultural and philosophical roots are to be uncovered for further comparative analysis.

On a more abstract level, one could imagine face as a bridging concept between interpersonal interaction and social order in the sense that face, at the micro-level of verbal and nonverbal behavior, encapsulates and dynamically displays the manifestations of (macro-level) cultural values. Situated discourse would thus become the epistemological locus where observation and interpretation of face and face-work take place as within their most expressive environment. Alongside psychologists, anthropologists, and sociologists, in future social theorists may be called upon to explore a powerful construct that thus far has occupied but not yet exhausted the endeavors of most politeness scholars.

Factivity

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Factivity is a semantic property of certain predicates, factive predicates, which take an embedded S-structure, preferably a *that* clause, as subject or object. The *that* clause of a factive predicate P is presupposed to be true when P is the main lexical predicate of a main clause (directly under a speech act of assertion, question, wish, command, etc.). Examples of factive predicates with factive object clauses are *know*, *realize*, and *have forgotten*. Usually the so-called affective factives are included, such as *regret*, *deplore*, and *be delighted*. (*Un*)*forgivable*, *pity*, and *regrettable* are predicates with factive subject clauses. Thus, *What a pity that she has left* presupposes that she has left. And *He hasn't forgotten that Jack played a trick on him* (with presupposition-preserving *not*) presupposes that Jack played a trick on him.

Europe and North America), the concern for face remains nevertheless relevant, even if expressed in a more understated way.

The consolidation of psychology research on the social self and social identity has opened up new contexts of relevance for the dynamics of face and face-work, calling on a modified model of face and politeness that breaks free from the straitjacket of cognitivist psychology. Factivity

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Factivity is a semantic property of certain predicates, factive predicates, which take an embedded S-structure, preferably a *that* clause, as subject or object. The *that* clause of a factive predicate P is presupposed to be true when P is the main lexical predicate of a main clause (directly under a speech act of assertion, question, wish, command, etc.). Examples of factive predicates with factive object clauses are *know*, *realize*, and *have forgotten*. Usually the so-called affective factives are included, such as *regret*, *deplore*, and *be delighted*. (*Un*)*forgivable*, *pity*, and *regrettable* are predicates with factive subject clauses. Thus, *What a pity that she has left* presupposes that she has left. And *He hasn't forgotten that Jack played a trick on him* (with presupposition-preserving *not*) presupposes that Jack played a trick on him.

Sometimes a predicate may take a sentential subject as well as a sentential object clause. Such double-complementation predicates are invariably factive with respect to their subject clause. For example, a sentence such as *That the butler had blood on his shirt suggested that he was the murderer* presupposes that the butler had blood on his shirt. This is a general, and so far unexplained, property of verbs that take double complementation.

Factive verbs are intensional in that they block *substitution salva veritate* of coreferential terms: *Luke realizes that the Morning Star is uninhabited* does not have the same truth conditions as *Luke realizes that the Evening Star is uninhabited*.

Some predicates are 'antifactive,' in that they induce a presupposition of the **falsity** of the embedded *that* clause. For example, *be under the illusion* is an antifactive predicate (likewise for the German *wähnen*, used by Frege (1892: 47) in the first modern observation of factivity).

In modern times, factivity was brought to the attention of the linguistic world by Kiparsky and Kiparsky (1971), who pointed out that factivity is not only a semantic but also a syntactic property, as factive predicates share a number of syntactic properties, in particular the impossibility of Subject Raising from the embedded clause, and the possibility of replacing *that* with the complex NP *the fact that*. The only exception is the prototypical factive verb *know*, which behaves syntactically as a nonfactive verb. This problem may be solved by assuming that *know* has lexically incorporated the NP *the fact* as part of its object clause, reducing the complex NP *the fact that* to the simple complementizer *that*.

Canon Falc'hun was born in 1909 into a peasant family of North Finistère so he was a native speaker of Breton. He went to Lesneven College (or '*petit-séminaire*') and prepared for priesthood in the Grand-Séminaire of Quimper. Soon after his ordination, he asked his bishop for authorization to go to Paris to study phonetics and Celtic studies. A researcher in the Centre National de la Recherche Scientifique from 1939 on, he became a lecturer (1944) and Professor of Celtic (1952) in the Arts Faculty of Rennes. When Brest University was founded, he transferred there, which was near his own birthplace. From the age of 20 he suffered from tuberculosis, which obliged him to interrupt his work for long periods several times. He died in January 1991.

During his stay in Paris, Falc'hun recorded his own Breton language and studied its sounds with various instruments. He became particularly interested in 'initial mutations' in Breton, together with the exact pronunciation of consonant groups. His phonetic observations were also interpreted phonologically under the influence of M.-L. Sjoestedt-Jonval (Professor of Irish in the Ecole Pratique des Hautes Etudes), who had written a thesis on the phonology of Kerry Irish. According to Falc'hun, Breton consonants are divided into strong (*fortes*) and soft (*douces*, *lenes*), in 12 pairs. In a stressed syllable (that is, in the penultimate for most of the dialects), a strong consonant always follows a short vowel, and a soft consonant follows a long vowel. The initial mutation, called 'lenition' (voicing of voiceless stops, spirantization of voiced stops, etc.), is based on the opposition between strong and soft consonants: in the case of resonants, the strong variants are softened by the 'lenition.' This mutation occurs in every context where the word would have been originally preceded by a word with a vocalic ending: the following initial consonant has been assimilated to the vowel,

Sometimes a predicate may take a sentential subject as well as a sentential object clause. Such double-complementation predicates are invariably factive with respect to their subject clause. For example, a sentence such as *That the butler had blood on his shirt suggested that he was the murderer* presupposes that the butler had blood on his shirt. This is a general, and so far unexplained, property of verbs that take double complementation.

Factive verbs are intensional in that they block *substitution salva veritate* of coreferential terms: *Luke realizes that the Morning Star is uninhabited* does not have the same truth conditions as *Luke realizes that the Evening Star is uninhabited*.

Some predicates are 'antifactive,' in that they induce a presupposition of the **falsity** of the embedded *that* clause. For example, *be under the illusion* is an antifactive predicate (likewise for the German *wähnen*, used by Frege (1892: 47) in the first modern observation of factivity).

In modern times, factivity was brought to the attention of the linguistic world by Kiparsky and Kiparsky (1971), who pointed out that factivity is not only a semantic but also a syntactic property, as factive predicates share a number of syntactic properties, in particular the impossibility of Subject Raising from the embedded clause, and the possibility of replacing *that* with the complex NP *the fact that*. The only exception is the prototypical factive verb *know*, which behaves syntactically as a nonfactive verb. This problem may be solved by assuming that *know* has lexically incorporated the NP *the fact* as part of its object clause, reducing the complex NP *the fact that* to the simple complementizer *that*.

Canon Falc'hun was born in 1909 into a peasant family of North Finistère so he was a native speaker of Breton. He went to Lesneven College (or '*petit-séminaire*') and prepared for priesthood in the Grand-Séminaire of Quimper. Soon after his ordination, he asked his bishop for authorization to go to Paris to study phonetics and Celtic studies. A researcher in the Centre National de la Recherche Scientifique from 1939 on, he became a lecturer (1944) and Professor of Celtic (1952) in the Arts Faculty of Rennes. When Brest University was founded, he transferred there, which was near his own birthplace. From the age of 20 he suffered from tuberculosis, which obliged him to interrupt his work for long periods several times. He died in January 1991.

During his stay in Paris, Falc'hun recorded his own Breton language and studied its sounds with various instruments. He became particularly interested in 'initial mutations' in Breton, together with the exact pronunciation of consonant groups. His phonetic observations were also interpreted phonologically under the influence of M.-L. Sjoestedt-Jonval (Professor of Irish in the Ecole Pratique des Hautes Etudes), who had written a thesis on the phonology of Kerry Irish. According to Falc'hun, Breton consonants are divided into strong (*fortes*) and soft (*douces*, *lenes*), in 12 pairs. In a stressed syllable (that is, in the penultimate for most of the dialects), a strong consonant always follows a short vowel, and a soft consonant follows a long vowel. The initial mutation, called 'lenition' (voicing of voiceless stops, spirantization of voiced stops, etc.), is based on the opposition between strong and soft consonants: in the case of resonants, the strong variants are softened by the 'lenition.' This mutation occurs in every context where the word would have been originally preceded by a word with a vocalic ending: the following initial consonant has been assimilated to the vowel,

resulting in softening. In his phonetic analysis of stops and spirants, Falc'hun also suggested a possible explanation for the Germanic *Lautverschiebung*. His phonetic analysis of Breton consonants was published in 1951 as a part of his thesis.

As a consequence of these observations, in the years 1954–1955 Canon Falc'hun planned a reform of Breton orthography. This was later called the 'University spelling.' He felt the need for two different spellings for the velar spirants (the voiced and the voiceless). As the final stops of Breton do not have a voice opposition, he proposed to distribute the corresponding letters (-t/-d, c/-g) according to morphological classes.

His main thesis was devoted to 'linguistic geography': he maintained that the analysis of dialect maps on its own can enable us to understand the history of a language. Basing his study on the *Atlas Linguistique de la Basse-Bretagne*, by Pierre Le Roux (*see* **Le Roux, Pierre (1874–1975)**), he drew the different isoglosses, trying to establish the main frontiers between the dialects. Though his historical conclusions were fairly rational (as, for example, an innovating center in Carhaix, and archaizing zones in NW and SE), they sometimes suggested erroneous assumptions about what was archaic and what was not: Jackson (*see* **Jackson, Kenneth Hurlstone (1909–1991)**) later proved that the analysis of isoglosses on its own cannot lead one to differentiate archaisms and innovations.

Toward the end of his career, Canon Falc'hun wrote many articles and books on more popular subjects, most of which are condemned to oblivion. He was unfortunately unable to meet the scientific requirements of linguistic history and comparative grammar. His fantastic etymologies, his idea of a direct filiation between Gaulish and Breton, and his supposed 'Gaulish article' are all to be rejected.

Falkland Islands: Language Situation

A Sudbury, King's College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The Falkland Islands comprise two large islands (East and West Falkland) and more than 300 smaller islands covering an area slightly larger than Jamaica. They are situated in the South Atlantic 12 800 km south of the United Kingdom and 480 km east of South America. Approximately 2500 people reside in the islands, with three-quarters living in Stanley, the capital and the only town located on the east of East Falkland, and the remainder living around the islands in settlements ranging in size from three to more than 30 people. (An additional 2000 to 3000 military and military-associated personnel are based in the islands at any one time.) All settlements outside Stanley and the land itself are collectively known as Camp, derived from the Spanish word *campo*, meaning 'countryside'. The islands have been English speaking since the 1830s, when a permanent British settlement was established on the previously uninhabited islands. This makes the English spoken in the Falkland Islands one of the youngest native Englishes in the world.

Regional Variation

The geographical isolation and small population of many of the Camp settlements has led to the assumption that different dialects emerged in different Camp settlements and closely resembled the English of the original settlers. In Stanley, by contrast, a new, southern-hemisphere dialect of English has emerged (Trudgill, 1986). This report is very likely to have been accurate in the early to mid 20th century and probably before the 1982 conflict between the United Kingdom and Argentina over sovereignty of the islands. However, in recent decades the increase in United Kingdom immigration to the islands and improved transport and communication links within the islands and to the outside world have resulted

resulting in softening. In his phonetic analysis of stops and spirants, Falc'hun also suggested a possible explanation for the Germanic *Lautverschiebung*. His phonetic analysis of Breton consonants was published in 1951 as a part of his thesis.

As a consequence of these observations, in the years 1954–1955 Canon Falc'hun planned a reform of Breton orthography. This was later called the 'University spelling.' The Falkland Islands comprise two large islands (East and West Falkland) and more than 300 smaller islands covering an area slightly larger than Jamaica. They are situated in the South Atlantic 12 800 km south of the United Kingdom and 480 km east of South America. Approximately 2500 people reside in the islands, with three-quarters living in Stanley, the capital and the only town located on the east of East Falkland, and the remainder living around the islands in settlements ranging in size from three to more than 30 people. (An additional 2000 to 3000 military and military-associated personnel are based in the islands at any one time.) All settlements outside Stanley and the land itself are collectively known as Camp, derived from the Spanish word *campo*, meaning 'countryside'. The islands have been English speaking since the 1830s, when a permanent British settlement was established on the previously uninhabited islands. This makes the English spoken in the Falkland Islands one of the youngest native Englishes in the world.

Regional Variation

The geographical isolation and small population of many of the Camp settlements has led to the assumption that different dialects emerged in different Camp settlements and closely resembled the English of the original settlers. In Stanley, by contrast, a new, southern-hemisphere dialect of English has emerged (Trudgill, 1986). This report is very likely to have been accurate in the early to mid 20th century and probably before the 1982 conflict between the United Kingdom and Argentina over sovereignty of the islands. However, in recent decades the increase in United Kingdom immigration to the islands and improved transport and communication links within the islands and to the outside world have resulted

in such regional differences becoming less marked and a more homogenized variety of Falkland Islands English developing.

Social Variation

There is little in the way of variation along a socially-stratified continuum in Falkland Islands English, presumably as a result of the very small population and consequent lack of social class boundaries. However, in early Falklands history a small number of landowning settlers was sent to the United Kingdom for education, which resulted in a small group of near-received-pronunciation speakers.

Phonology/Phonetics

Phonemically Falkland Islands English is a Southern British variety sharing the phonemic system of Southern Britain and the other southern hemisphere Englishes. Phonetically, however, there are a number of differences between Falkland Islands English and the other southern hemisphere Englishes (New Zealand English, Australian English, and South African English), and there is also a high level of both inter- and intraspeaker variability. Key phonetic features of Falkland Islands English include the following:

- Nonraising of the front short vowels in TRAP, DRESS, and KIT, by contrast with the other southern hemisphere Englishes
- Weak allophonic distribution of the MOUTH and PRICE diphthongs, according to the pattern of Canadian Raising (Chambers, 1973)
- Tendency toward a long front realization of BATH/START/PALM lexical sets
- Gradual focusing on schwa in unstressed syllables

In terms of intonation, Falkland Islands English shares high raising terminals at the end of statements with the other southern hemisphere Englishes.

Syntax

Falkland Islands English has few grammatical features that distinguish it from Southern British English.

Lexicon

There is a small amount of island-specific vocabulary in Falkland Islands English, particularly in comparison with other southern hemisphere Englishes. The majority of local lexical items derive from Spanish and are connected with horse-riding gear and place names, most likely a legacy of 19th century South American gauchos who worked transiently in the islands. Such loanwords have been 'Falklandized' and have distinctive Falkland Islands English pronunciations, almost unrecognizable from the Spanish. Examples include the place name *Tranquilidad*, pronounced [triŋkəli:da:], and *rebenque* 'whip', which is pronounced [rəvɪnki:].

False Friends

P Chamizo-Domínguez, Universidad de Málaga, Málaga, Spain

© 2006 Elsevier Ltd. All rights reserved.

The term 'false friends' (*faux amis*, in French) was coined by M. Koessler and J. Derocquigny (1928) in their classical, seminal work on this topic. From a synchronic point of view, the linguistic phenomenon of false friends can be defined as the fact that two given words are similar or equivalent graphically or phonetically in two or more given languages but have different meanings. In other words, false friends share their signifiers, but they do not share their meanings. For that reason, false friends are extremely insidious traps for translators. To illustrate just how problematic false friends can become, take the Spanish term for them, *falsos amigos* – now widely used in linguistics and translation studies; it results from inadequate translation of French *faux amis*. In Spanish, a treacherous, disloyal, or unfaithful friend is not properly called *un falso amigo*, but *un mal amigo*, literally 'a

False Friends

P Chamizo-Domínguez, Universidad de Málaga, Málaga, Spain

© 2006 Elsevier Ltd. All rights reserved.

The term 'false friends' (*faux amis*, in French) was coined by M. Koessler and J. Derocquigny (1928) in their classical, seminal work on this topic. From a synchronic point of view, the linguistic phenomenon of false friends can be defined as the fact that two given words are similar or equivalent graphically or phonetically in two or more given languages but have different meanings. In other words, false friends share their signifiers, but they do not share their meanings. For that reason, false friends are extremely insidious traps for translators. To illustrate just how problematic false friends can become, take the Spanish term for them, *falsos amigos* – now widely used in linguistics and translation studies; it results from inadequate translation of French *faux amis*. In Spanish, a treacherous, disloyal, or unfaithful friend is not properly called *un falso amigo*, but *un mal amigo*, literally 'a

bad friend.' Although 'false friends' is the most common term applied to the phenomenon under discussion, other names, such as *false equivalents* and *false cognates,* also have been used (Buncic, 2000). Nevertheless, it should be stressed that the concepts of false friends and false cognates (from Latin *cognatus*, 'relative') are quite different because all false cognates are false friends but not all false friends are false cognates. For instance, Italian *burro* 'butter' and Spanish *burro* 'ass, donkey' are false cognates and false friends. By contrast, French *personne* 'nobody' and English *person* are false friends but, given that they are etymologically related, they aren't false cognates. In other words, the set of false friends includes the set of false cognates but not vice versa.

False friends can be classified in two groups: **chance false friends** and **semantic false friends**.

Chance false friends are those words that are similar or equivalent in two or more given languages but without any semantic or etymological reason for this overlap. The English noun *coin* and the French noun *coin* 'corner' have exactly the same graphic shape because of a fortuitous diachronic process. Similarly, the Portuguese word *chumbo* 'lead' and the Spanish noun *chumbo* 'Indian fig, prickly pear' are not etymologically related at all. In fact, chance false friends could be considered as the equivalents, in two or more given languages, of homonymic words in a single natural language. Such false friends also are false cognates.

Semantic false friends are those words that are similar or equivalent in two or more languages because they are etymologically related. That is, semantic false friends have the same etymological origin but have developed different meanings in each language. For that reason, semantic false friends could be considered the equivalents, in two or more given languages, of polysemous words in a single natural language. Semantic false friends can in turn be divided into two groups: (1) full false friends, which are those words that have completely different meanings; and (2) partial false friends, which are those words that have several senses, some of which coincide in both languages whereas others do not. The Spanish word *bigote* 'moustache,' English *bigot,* and French *bigot/bigote* are cases of full false friends because there is no possible context in which the Spanish word can be (correctly) translated into the English or French words. By contrast, Spanish *actual*, French *actuel/actuelle* and German *aktuell* are only partial false friends with regards to English *actual* because, although all three usually mean in ordinary language 'up-to-date' or 'current,' they also can mean *actual* 'real, existing in fact' in philosophical jargon. The English noun *injury* is another perfect example of a partial false friend with regard to Spanish *injuria*, Portuguese *injúria*, and French *injure*. *Injury*, *injuria*, *injúria*, and *injure* are rooted in Latin *injuria* 'offence, injustice.' Spanish, Portuguese, and French have more or less kept the original Latin meaning of that word. As a consequence, the Spanish, Portuguese, and French terms are not false friends with regard to the English one, in which *injury* is a synonym for 'insult,' 'offence,' or 'injustice.' But the English term is also used metaphorically and/or euphemistically to mean 'wound'. So that when *injury* is a synonym for 'wound' we are dealing with a false friend with regard to *injuria*, *injúria*, and *injure*. This means that certain word plays and double entendres that are possible in English are impossible in Spanish, Portuguese, or French: for instance, the play on words in *The resulting lawsuit injured her more than the actual automobile accident had done*.

The study and knowledge of semantic false friends is especially interesting and beneficial for translators. When false friends are etymologically related, speakers may fail to recognize that their meanings are quite different. Usually the hearer or reader of a translation can detect erroneously translated false friends by means of a pragmatic strategy when detecting an inconsistency in the text. Nevertheless, there are also cases in which the translated text or utterance may make sense, but what the hearer/reader understands may be quite different from what the speaker or writer was trying to say (Chamizo-Domínguez and Nerlich, 2002).

As words change their meanings inside a single language, false friends develop by one or or more well-known mechanisms; namely, metaphor, amplification or restriction of meaning, amelioration or pejoration, metonymy, borrowings, euphemism or dysphemism, irony, and so on (Chamizo-Domínguez and Nerlich, 2002).

Let us consider some examples.

1. Metaphor. In addition to its literal meaning, the Spanish noun *canguro* 'kangaroo' has developed the metaphorical meaning (now lexicalized and widely used) of 'babysitter,' whereas the English word has not developed any such metaphorical meaning, except perhaps in the collocation 'kangaroo court', i.e., 'illegal court.'

2. Amplification of meaning. The Spanish adjective *inexcusable* shares the meaning of 'indefensible, unjustifiable, unpardonable' with its English cognate, but the Spanish word, in addition, has amplified this shared meaning and also means 'unavoidable.'

3. Amelioration/pejoration. The English noun *topic* and the Spanish counterpart *tópico* 'commonplace' are perfect examples of semantic false friends. It should be stressed, however, that both words are related to the Greek word *topos* 'place, site' and have

emerged from an allusion to Aristotle's work *Topics*. *Topic* has become a synonym for 'subject of a text or discourse' in English because of a process of amelioration through which the standard meaning of the Greek term changed its meaning. By contrast, the standard meaning of the Spanish word *tópico* is the outcome of a process of pejoration, a process which sent the word in the opposite direction semantically. So when an English lecturer teaches *a topic* she/he can be regarded as an excellent teacher, whereas a Spanish one who teaches *un tópico* can be regarded as a terrible teacher. By contrast, the French cognate *topique* (mainly used in medical jargon) has kept a meaning very close to the usual meaning of Greek *topos*.

4. Metonymy. Take the case of the Spanish word *baño* and the French word *bagne*. Both derive from Latin *balneum* 'bath, bath house,' but *baño* means 'bath' or 'bath house,' whereas *bagne* has the standard meanings of 'prison,' 'dungeon,' and 'hard labor,' as well as the slang or familiar meaning of 'work' or 'the site where a person works.' But in the past the Spanish word *baño* also meant 'prison' or 'dungeon', as illustrated by the title of the well-known work by Miguel de Cervantes, *Los baños de Argel* 'The dungeons of Algiers.' It has to be said, however, that few Spaniards (and that includes most scholars) know this old-fashioned meaning of *baño*. The meaning of 'prison' for *baño* and *bagne* originated in a metonymy based on the fact that the Turks used to imprison their captives inside Constantinople bath houses. From these initial conditions the following metonymic chain of semantic changes arose: (1) French has lexicalized the meaning of 'prison' for *bagne*; (2) by means of a second metonymy the meaning 'hard work' has become lexicalized in *bagne*; and (3) by means of a third (and perhaps humorous/ironic) metonymy the meaning of 'work' has been added. As a result of this diverging chain of metonymies the words *baño* and *bagne* have now become false friends, because, whereas French *bagne* is synonymous with *pénitencier*, *galères*, *enfer*, *préside*, or *travaux forcés*, current Spanish *baño* is not. Both words are false friends with regard to the English word *bagnio* that was borrowed from Italian *bagno* 'bath, bathing house' with the euphemistic meaning of 'brothel,' which was in use in English from the 17th to the 19th century and probably beyond.

5. Borrowings. Given that most words are polysemous, when a concrete term is borrowed it usually becomes a (partial) false friend by means of a restriction in meaning. English *check* has been borrowed by lots of languages but is restricted to the field of banking. Similarly, German has borrowed English adjective *soft* in the collocation *soft Eis*, but what Germans call *soft Eis* is what English speakers call *ice cream*.

6. Euphemism/dysphemism. Although the Latin word *latrina* (related to *lavare*, 'to wash') was coined as a euphemism for *cloaca*, it has acquired a dysphemistic flavor in most European language (e.g., English *latrine*, Spanish *letrina*, French *latrine*, or German *Latrine*), because it is used in barrack room contexts. As a result of this, English *latrine* and Latin *latrina* have become false friends because, if they are used in the same context, a different register is evoked and different implicatures arise.

7. Irony. Spanish *bárbaro/bárbara* has developed, in addition to the meanings of 'brute,' 'cruel,' 'inhuman,' or 'ferocious,' which are shared with English *barbaric/barbarous*, the ironic meaning (now widely lexicalized) of 'fantastic,' 'terrific,' 'great,' or 'super' (cf. colloquial English *wicked*).

When one of these kinds of semantic change takes place in a given language false friends are likely to arise. And this happens not only with common nouns, adjectives, and verbs but also with proper names. For instance, the Spanish toponym *Cabo de Hornos* 'Cape Furnaces' originated in the erroneous translation of English *Cape Horn* and/or Dutch *Kaap Hoorn* because of the graphic similarity between Spanish *horno* 'furnace' and the English or Dutch word. And, as a result of this erroneous translation, *Cabo de Hornos* and *Cape Horn/Kaap Hoorn* have become false friends.

Although false friends are usually analyzed as words in isolation, many terms only become false friends in the context in which they are used. In fact, there are numerous words that are not false friends at all when they are considered in isolation but that become false friends when they are part of an idiom. It should be stressed that most idioms can be understood both according to the literal meaning of their component words and according to any figurative interpretation. This figurative meaning becomes the most salient one when idioms are fully lexicalized. The literal translation of *French letter* (euphemism for 'condom') into French *lettre française* has only the literal meaning, 'letter in French.'

Family Speak

M Laforest, Université du Québec à Trois-Rivières, Trois-Rivières, Québec, Canada

© 2006 Elsevier Ltd. All rights reserved.

To work on family speak is to be interested in language as it is used in the private space. Family interactions have special features that make them a particularly revealing object of research. As in any interaction, power relationships exist, especially between parents and children (*see* **Power and Pragmatics**) But the intimacy that prevails in a family setting is unique: no other context presents so great a degree of proximity between participants or so great a volume of shared references owing to a common past (*see* **Shared Knowledge**). The intimacy of the family context affects discourse in three ways: (1) informality, since family speak is the most informal discourse there is, (2) the major role played by implicit understanding due to shared references, and (3) the particularly high number of metapragmatic or metadiscursive comments (especially in exchanges with children), since the home is a privileged venue for pragmatic learning (*see* **Language Socialization; Metapragmatics**).

Work on family discourse allows us to reconsider some important issues in pragmatics, namely:

1. The socialization of children. The family is the matrix of socialization and of the constitution of identity. As a result, family interactions offer an ideal means for observing processes involved in the acquisition of pragmatic competencies and the transmission of social and cultural values. Various strategies related to these processes have been studied, notably the use of control acts (particularly well documented), topic management, and metapragmatic comments. Narrative and explanatory talk have also been the object of interesting studies (*see* **Narrativity and Voice**). Several of the works listed were conducted from a cross-cultural perspective and highlight the differences observed from one linguistic community to another (*see* **Scaffolding in Classroom Discourse; Pragmatics: Overview**).
2. Politeness. In canonical models of politeness (notably Brown and Levinson, 1987), face-threatening acts (FTAs) are classified based on how directly or indirectly they are carried out, and the greatest politeness is associated with the greatest degree of indirection. It appears, however, that nagging, insults, complaints, and other FTAs occur frequently in family conversations, often in a direct form, without causing a deterioration in the family climate. These acts are not perceived as crude. In family speak, therefore, the direct nature of the act does not indicate impoliteness, and facework is done differently. By documenting how FTAs occur in the context of intimacy, works on family speak therefore help relativize the scope of norms that some consider universal in terms of politeness (*see* **Politeness; Face**).

Fanagalo

R Mesthrie, University of Cape Town, Cape Town, South Africa

© 2006 Elsevier Ltd. All rights reserved.

Fanakalo (also spelled Fanagalo) is a southern African pidgin language that continues to be used two centuries after its inception. It is used in parts of South Africa, Zimbabwe (where it is usually known as Chilapalapa), Mozambique, Malawi, Zambia, and Namibia where it has been carried by migrant workers in the South African mines. Within South Africa it is spoken mainly in the provinces of KwaZulu-Natal and Gauteng (the mining area).

Fanakalo can be described as a 'crystallized' pidgin in terms of its fairly stable structure and circumscribed contexts of use. It is a contact language used prototypically in work situations: on farms, in the mines of the Witwatersrand that draw a multilingual workforce from all over southern Africa, in other urban labor situations, and in domestic employment (between employers and maids, cooks, gardeners). One can hear it in situations of sustained labor contacts, as well as in 'transactional' communications as in gas stations, shops, markets, and the like. In South Africa in provinces other than KwaZulu Natal and Gauteng, Fanakalo is less well known, as the rival urban lingua franca in the domain of labor is Afrikaans. In rural areas, population demographics often dictate that white farmers and their families acquire the local Bantu language, especially Tswana in the Free State, Xhosa in the eastern Cape, and Zulu in KwaZulu-Natal. In former times, Fanakalo was also used in nonlabor contexts when Europeans and/or Indians had no other means of communication with each other. Thus, it was used sporadically "by white men amongst themselves when no other means of communication are available" (Mayne, 1947: ii) and when North Indians had no other means of communication with South Indians (Mesthrie, 1989).

Fanakalo use is receding slightly as English spreads as a lingua franca among younger people, even on farms. In addition, its use is no longer officially sanctioned in the mines of post-apartheid South Africa because of its long-standing association with cheap labor and racism. However, there are still ample situations in which it is used, including some nonlabor contexts (Adendorff, 1995). Two such uses are a kind of expatriate solidarity or nostalgia for things South African expressed by some expatriates in light-hearted communications with family in South Africa or as a secret language for Zimbabwean or KwaZulu-Natal tourists abroad, especially for those who do not speak a Bantu language or Afrikaans. Fanakalo is sometimes used by Zulu speakers as a playful form of code divergence that signifies harsher relations with interlocutors than is possible using Zulu (Adendorff, 1995).

Origins

The first sustained contacts between Europeans and indigenous peoples in South Africa took place in the western Cape in the 17th century, where Afrikaans arose as a lingua franca out of the experience of colonization and slavery. When Afrikaners moved into the eastern Cape from about 1770 onward, Afrikaans was no longer a viable means of communication with the Xhosa people, and several strategies of communication arose: by signs, by simplified Xhosa, by simplified Afrikaans, or by a mixture of these methods (Mesthrie, 1998). With the arrival of the first batch of settlers from England, English was added to the frontier in 1820.

Fanakalo probably came into existence amid these diffuse communicational circumstances in the eastern Cape in the early 1800s. Mesthrie (1998: 13) gave the earliest recorded sentence in the pidgin as *Wena tandaza O Taay* 'You (must) worship God' (uttered by the missionary John Reid, Kat River 1816, who thought he was speaking Xhosa). Fanakalo does not seem to have been widespread in this period: It is but one of several communication strategies that appear in the archival and travel literature of the times, and judging from the sources it was used not very frequently.

Among the many diffuse strategies of communication on the eastern Cape frontier, the one that won out later in the new colony of Natal (established in 1843 further north along the coast) was the Fanakalo option. The pidgin, which was initially known as 'Kitchen Kaffir' in this colony, was likely brought over by people with experience of the frontier: Afrikaners away from the British in the Cape Colony, their 'colored' servants, English adventurers, and possibly some officials. No concrete evidence of this link exists, however, and the brief accounts of Fanakalo give a picture of a pidgin being invented anew from contacts between British settlers and the Zulus who outnumbered them. Two major crystallizing events for Fanakalo took place in this period: (1) the arrival of indentured Indians in large numbers in the coastal province of Natal (starting in 1860); and (2) the discovery of diamonds and gold in the interior (starting in 1867).

Structure

Although Fanakalo has none of the inflexional/agglutinative richness of Zulu (see Cole, 1953), it is not as impoverished as one might expect of a pidgin. It has four tense markers used with verbs, which are all derived from Zulu (or Nguni languages generally): *-a* (for infinitive, imperative, and present tense verbs); *-ile* (past tense); *zo* (future); and *gate* (anterior). The first two tense markers are suffixes, whereas the future marker *zo* occurs either as a free form that precedes the verb or as [z] cliticized to the subject pronoun. The fourth tense marker, *gate* (phonetically [gate] < Zulu *kade* 'long ago') is in the process of being grammaticalized for pluperfect and habitual past.

Other verb inflections, which are all taken from Zulu/Nguni, are the following:

-isa (causative), e.g., *theng-a* 'buy' versus *theng-isa* 'cause to buy, sell'
-wa (present passive), e.g., *phek-a* 'cook'; *phek-wa* 'is cooked'
-we (past passive), e.g., *phek-a* 'cook'; *phek-iwe* 'was cooked.'
-ela (benefactive), e.g., *theng-a* 'buy'; *theng-ela* 'buy for'-'Buy (a shirt) for (me)'

Linguistically, Fanakalo is typical of pidgins in that it cannot be classified in terms of existing language groupings; it is not quite Germanic or Nguni in structure. Its lexis and inflectional morphology stem largely from Nguni. Its syntax, however, seems to lean in the direction of the Germanic (more specifically English, rather than Afrikaans). Fanakalo is SVO in structure in main and subordinate clauses. It has none of the word-order rules of Afrikaans that place verbs at the end of subordinate clauses and at the end of main clauses that have an auxiliary in V2 position. Nor does it have the subject inversion rule of Afrikaans and of slightly archaic English that places a verb after an adverbial of time but before a subject (again in V2 position). Furthermore, there is no trace of a Zulu word-order rule that permits object pronouns to precede verbs as a clitic in unmarked (unemphatic) sentences. However, Fanakalo is not rigidly SVO insofar as it permits topic-comment order as well.

Phonetically, Fanakalo is subject to wide variation depending on the L1 of the speaker. The common core tends to use a five-vowel system (like Zulu) with two diphthongs, [ai] and [au], and to replace the clicks by velar /k/.

Fant, (Carl) Gunnar (Michael) (b. 1919)

O Fujimura, International Institute for Advanced Studies, Kizu, Kyoto, Japan

© 2006 Elsevier Ltd. All rights reserved.

Gunnar Fant was born on October 8, 1919. He obtained an electrical engineering degree in 1945 and Doctor of Science in 1958, from the Kungliga Tekniska Högskolan (Royal Institute of Technology, KTH) in Stockholm. After working at Ericsson Telephone Company and then spending two years at the Acoustics Laboratory and Physics Department of the Massachusetts Institute of Technology, he returned to KTH and headed its Speech Transmission Laboratory from 1951 to 1966. From 1966 to 1987, he was a professor at KTH, in charge of its newly founded Department of Speech Communications and Music Acoustics. He is currently Professor Emeritus and Senior Research Fellow at KTH.

Professor Fant is the founder of modern speech science, in particular, the acoustic theory of speech signal description, often cited as the source-filter

Fant, (Carl) Gunnar (Michael) (b. 1919)

O Fujimura, International Institute for Advanced Studies, Kizu, Kyoto, Japan

© 2006 Elsevier Ltd. All rights reserved.

Gunnar Fant was born on October 8, 1919. He obtained an electrical engineering degree in 1945 and Doctor of Science in 1958, from the Kungliga Tekniska Högskolan (Royal Institute of Technology, KTH) in Stockholm. After working at Ericsson Telephone Company and then spending two years at the Acoustics Laboratory and Physics Department of the Massachusetts Institute of Technology, he returned to KTH and headed its Speech Transmission Laboratory from 1951 to 1966. From 1966 to 1987, he was a professor at KTH, in charge of its newly founded Department of Speech Communications and Music Acoustics. He is currently Professor Emeritus and Senior Research Fellow at KTH.

Professor Fant is the founder of modern speech science, in particular, the acoustic theory of speech signal description, often cited as the source-filter

theory. Most current work in speech technology is based on this theory of vowels and consonants, as discussed in his monograph, *Acoustic theory of speech production* (1960). Based on this new theory, he created a speech synthesizer, implemented as an electrical circuit, resonant frequencies of which were controlled by moving a handle on a plane (OVE I). The quality of the artificially produced speech signals using this principle (series formant synthesis scheme with added circuits and an improved controlled scheme, OVE II) has not been surpassed, even by the most modern computer-based speech synthesis work. It provided solid experimental evidence for the accuracy of his approximation theory. Currently, he works on prosodic characteristics of speech signals, research well beyond the scope of his previous seminal work on segmental phonetics, in collaboration with Dr. Anita Kruckenberg.

An electrical engineer by training, his research reflects his deep interest in linguistics. Working with Professors Roman Jakobson and Morris Halle at the Acoustics Laboratory of MIT in the early 1950s, he co-authored *Preliminaries to speech analysis,* the foundation of distinctive feature theory. Fant's students include Professors Sven Öhman of Uppsala University and Björn Lindblom of Stockholm University, both in the Linguistics Department. Professor Johan Sundberg, in charge of the Music Section of the Department of Speech Communication and Music Acoustics, KTH, was also one of Fant's students. Many internationally prominent speech researchers, including some from Eastern Europe and East Asia, have conducted research in Fant's Speech Transmission Laboratory. Their backgrounds vary widely, including phonetics, linguistics, experimental psychology, speech science, engineering, and physics, representing leading institutions such as MIT, Bell Laboratories, and Haskins Laboratories.

Professor Fant is a member of the Royal Swedish Academy of Engineering Sciences (Gold Medal, 1959), the Royal Swedish Academy of Science (Large Gold Medal, 1998), the American Academy of Arts and Sciences, and the U.S. National Academy of Engineering, and is a Fellow of the Acoustical Society of America (Silver Medal, 1980) and of the European Speech Communication Association (Gold Medal, 1989).

Faroe Islands: Language Situation

M P Barnes, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The Faroes were settled by Scandinavians about AD 800. There was no indigenous population, so the language of the islands came to be based entirely on the speech of the settlers, most of whom seem to have hailed either directly or indirectly from western Norway. By the time of the Reformation, the Faroes, together with Norway, were ruled from Denmark. Danish became the language of public discourse in the islands, and the sole written medium. Although all the Scandinavian tongues have a common origin, 16th-century Faroese and Danish were almost certainly no longer mutually comprehensible, so the natives were compelled to learn a modicum of the rulers' language in order to deal with authority and participate in church services. The degree to which the Faroese mastered the new tongue doubtless varied, but by the latter half of the 18th century Danish influence on the native idiom was so strong that one influential writer proposed abandoning Faroese altogether.

The advent of National Romanticism in the 19th century saw the development of an etymologically based (effectively Icelandic) orthography for Faroese, and the publication of a grammar of the language. Although subject to criticism for being too far removed from spoken forms, the new orthography was adopted by almost all who began to write and print in Faroese, and is still in use today. The last 150 years have seen the status of Faroese grow to the point where it is now the principal language of the islands, used in administration, church, education and the media. Nevertheless, Danish remains an official language, which all inhabitants of the Faroes are required to learn thoroughly. Even though granted home rule in 1948, the islands are still part of the Danish realm. And with the estimated number of Faroese speakers put at around 60 000 (of whom some 44 000 are resident in the islands, together with perhaps 1000 Danish speakers), linguistic self-sufficiency is hard to achieve. There is a lack of textbooks in Faroese in

theory. Most current work in speech technology is based on this theory of vowels and consonants, as discussed in his monograph, *Acoustic theory of speech production* (1960). Based on this new theory, he created a speech synthesizer, implemented as an electrical circuit, resonant frequencies of which were controlled by moving a handle on a plane (OVE I). The quality of the artificially produced speech signals using this principle (series formant synthesis scheme with added circuits and an improved controlled scheme, OVE II) has not been surpassed, even by the most modern computer-based speech synthesis work. Faroe Islands: Language Situation

M P Barnes, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The Faroes were settled by Scandinavians about AD 800. There was no indigenous population, so the language of the islands came to be based entirely on the speech of the settlers, most of whom seem to have hailed either directly or indirectly from western Norway. By the time of the Reformation, the Faroes, together with Norway, were ruled from Denmark. Danish became the language of public discourse in the islands, and the sole written medium. Although all the Scandinavian tongues have a common origin, 16th-century Faroese and Danish were almost certainly no longer mutually comprehensible, so the natives were compelled to learn a modicum of the rulers' language in order to deal with authority and participate in church services. The degree to which the Faroese mastered the new tongue doubtless varied, but by the latter half of the 18th century Danish influence on the native idiom was so strong that one influential writer proposed abandoning Faroese altogether.

The advent of National Romanticism in the 19th century saw the development of an etymologically based (effectively Icelandic) orthography for Faroese, and the publication of a grammar of the language. Although subject to criticism for being too far removed from spoken forms, the new orthography was adopted by almost all who began to write and print in Faroese, and is still in use today. The last 150 years have seen the status of Faroese grow to the point where it is now the principal language of the islands, used in administration, church, education and the media. Nevertheless, Danish remains an official language, which all inhabitants of the Faroes are required to learn thoroughly. Even though granted home rule in 1948, the islands are still part of the Danish realm. And with the estimated number of Faroese speakers put at around 60 000 (of whom some 44 000 are resident in the islands, together with perhaps 1000 Danish speakers), linguistic self-sufficiency is hard to achieve. There is a lack of textbooks in Faroese in

some subjects, especially at higher levels; magazines and trivial literature tend to be in Danish, as do many television programs (when not American); and most forms of higher education have to be pursued in Denmark or elsewhere abroad.

Spoken Faroese is still strongly influenced by Danish, especially the lexicon. In the light of the political and social history of the islands, this encroachment has led to the adoption of a purist policy for the written language and for public discourse. It is argued that unless a clear line of demarcation is drawn, Faroese could yet become so inextricably mixed with Danish it would effectively cease to have an independent existence. Dictionaries have reflected this policy by excluding hundreds of words in everyday spoken use on the grounds that they are Danish, while listing many Faroese neologisms created to replace Danish or international terms (e.g., *telda* 'computer,' derived from *telja* '[to] count,' *ferðaseðil* 'ticket,' literally 'journey paper,' for which the spoken language uses *bilett* from Danish/French *billet*). Recently the purist line has been attacked by some, who see written Faroese as artificial and too far removed from the spoken idiom. With increasing internationalization, linguistic attitudes may well change.

Early Views

What are speech sounds composed of? An early answer to this question was that speech sounds are definable as 'bundles' of simultaneous features having no internal organization (Bloomfield, 1933). However, a number of observations beginning in the mid 20th century called this view into question. A first discovery, stemming from such work as Hockett (1942), Harris (1944), Firth (1957), and others, was that features may have different scope across the segments of which a word or phrase is composed. A 'long component' (Harris) or 'prosody' (Firth), such as emphasis in Arabic or vowel harmony in Turkish, typically extends over many segments. Even more strikingly, perhaps, the study of the tone languages of Africa and elsewhere has shown that tones are typically asynchronic with segments, in the sense that several tones can be sequenced on a single syllable, giving rise to contour tones, while single tones can extend across several syllables. Some morphemes have been found to consist of tones alone, and most spectacularly, tones can 'float,' exerting a decisive influence on the tone contour of an utterance despite having no segmental realization themselves (for reviews of these and other 'nonlinear' properties of tone systems, see Goldsmith, 1990; Yip, 2002). Work in autosegmental phonology and related frameworks has brought to light many analogues to these properties among segmental features.

If features are not organized into unstructured 'bundles,' what is their organization? Earlier work in phonology gave scant attention to this question, though there were suggestions, from time to time,

that features could be classified into related classes or families and that such families could behave as units in regard to phonological processes (see, e.g., Trubetzkoy, 1969; Lass, 1975). The view that has gained most currency in recent work, from Clements (1985) to Padgett (2002), is that features are structured into *feature classes*, which combine in various ways to form higher-level units – notably the familiar consonant and vowel segments, but also incompletely specified subsegments. If features play a role in modern phonological theory similar to that of the atom in physics, feature classes play a role similar to that of the molecule: thus, segments are assigned a quasimolecular structure in which each 'molecule' corresponds to an independent articulator of the vocal tract (the tongue, the lips, the velum, the glottis, etc.). A further level of organization groups these smaller classes into larger classes corresponding to composite articulatory structures such as the oral cavity or the larynx. The resulting structure forms a comprehensive hierarchy of features.

Feature Geometry

This conception can be formalized in different ways. One well-known approach is that called *feature geometry*. This approach proposes to characterize feature structure within the general framework of autosegmental phonology. It addresses questions such as the following:

- What is the internal structure of speech sounds?
- How do speech sounds interact in phonological systems?
- What are possible and impossible phonological processes?

In its earliest and simplest form (Clements, 1985, drawing upon earlier suggestions by Mascaró and Mohanan), the basic premises of feature geometry are the following:

(1) a. Features may be grouped into feature classes.
b. Classes form a strict hierarchy that can be represented as a rooted tree.
c. This hierarchy is universal (identical in all languages).
d. Each feature and feature class is represented as a node on a separate autosegmental tier.
e. Each such node links to elements of just one higher-level tier.

This conception of feature organization can be illustrated by the tree structure in Figure 1, which shows the (highly simplified) representation of the doubly articulated labial velar stop [kp], found in many African languages. (The English speaker can approximate this sound by attempting to pronounce the word *backpack* without the initial *ba*.)

Figure 1 Organization of features in the sound [kp].

In this diagram, the Root node dominates all features. The Laryngeal, Oral Cavity, and Place nodes are intermediate class nodes, and [−spread glottis], [−voiced], etc., are the features themselves, constituting terminal nodes of the tree. Each node (including the features) is placed on a separate line representing an independent autosegmental tier. Note that features on different tiers are not ordered with respect to one another; for instance, [labial] neither 'precedes' nor 'follows' [dorsal]. Figure 1 illustrates the various properties in (1): (1a) features are grouped into classes, (1b) classes form a strict heirarchy, (1c) the hierarchy is universal by hypothesis, (1d) each feature and class is represented as a separate node on a separate tier, and (1e) each node links to the elements of just one higher-level tier. It follows from the latter assumption that features belong to (at most) one immediately superior class; thus, for example, no feature can link to both the Laryngeal node and the Place node.

How is the membership of feature classes determined? In feature geometry, classes are determined *functionally* rather than phonetically. A set of features forms a class if it behaves as a cohesive unit with regard to phonological statements and processes. As an example, let us consider NC (nasal + consonant) clusters in Spanish. The phoneme /n/ of the article *un* has several realizations, depending on the sound that follows. Examples are shown in Table 1.

If the following sound is a vowel or glide, as in the last example in Table 1, /n/ is realized as a dental sound. But if the following sound is a consonant, /n/ acquires its place of articulation, being realized as labial before the /p/ of *pulpo*, velar before the /g/ of

Table 1 Place assimilation across word boundaries in Spanish

u[m] pato	'a duck'	(labial)
u[ŋ] gato	'a cat'	(velar)
u[n] topo	'a mole'	(dental)
u[n̠] choco	'a cuttlefish'	(post-alveolar)
u[n] oso	'a bear'	(dental)

Table 2 Word-internal place assimilation in Spanish

ca[m]po	'field'	(labial)
ca[n]to	'chant'	(dental)
ca[n̠]cho	'rock'	(postalveolar)
ca[ŋ]co	'flower pot'	(velar)

gato, and so forth. The same preconsonantal distribution is found within words, as shown by the examples in Table 2.

These examples show that the various features that define the property 'place of articulation' behave as a single unit in Spanish. Rather than the assimilation rule's being stated in terms of each individual place feature ("/n/ is realized as [labial] before labial sounds, [dorsal] before dorsal sounds," etc.), it may be stated once and for all by making reference to the Place node, which groups all oral cavity place features together: "Nasal consonants share the Place node with a following consonant." The NC cluster is accordingly treated as a linked sequence comprising internally sequenced manner features ([+nasal] followed by [−nasal], etc.) but a single Place specification, as shown by the representation of relevant features of *ninfa* [nimfa] 'nymph' in Figure 2.

Each segment is said to be 'characterized' by the features it dominates in the tree. Thus [m] is characterized as [labial], [+nasal], and [−continuant], while [f] is characterized as [labial], [−nasal] and [+continuant]. The fact that the nasal acquires a labiodental rather than a bilabial realization can be explained on the assumption that the Place node receives a uniform articulatory interpretation at the phonetic level.

As this example illustrates, the Place node has been determined on purely phonological grounds, following the observation that in Spanish, as in many other languages, all place features constitute a functional unit. As place features tend to behave as a single group across languages, they are gathered into a single Place class. Though phonetic considerations were not used as a criterion in setting up this class, it is not a phonetically arbitrary one, but comprises the set of features that define the location of the primary constriction of a segment in the oral cavity. In this case (and others), the feature classes brought to light by the study of phonological patterns prove to have certain phonetic properties in common. This is surely not an accident, but shows that the feature hierarchy has its phonetic basis in speech articulation. The complete feature hierarchy resembles a simplified image of the vocal tract, in which each class represents a functionally independent articulator or articulator set.

Given these various observations, we may formulate the following claim:

(2) Phonological statements (rules, constraints) take single nodes as arguments.

This means that phonological statements may operate only on single nodes in the tree. Place of articulation assimilation in Spanish provides a good illustration; this rule targets a single node (the Place node), requiring that nasal consonants must share this node with the following consonant in the word or phrase. The empirical interest of (2) in cross-linguistic perspective is that it heavily constrains the set of imaginable phonological rules, dividing them into two classes: 1) possible rules, 2) impossible rules. Spanish nasal assimilation is a possible rule, as it conforms to (2); but a similar rule requiring a nasal consonant to assimilate to a following consonant in terms of an arbitrary set of features, such as [labial], [voiced], and [lateral], would not meet this criterion, as no single node groups just these features and no others. A great deal of research has tended to corroborate this claim, at least for the better-understood features; for example, the arbitrary rule just stated is unattested across languages, as far as we know. One of the major results of work in feature geometry has been its ability to provide a much narrower characterization of the notion 'possible rule,' and hence 'possible process,' than has been achieved in other approaches.

Later Developments of Feature Geometry

The rather simple conception outlined above has been modified and elaborated in later work. A first development came from the work of McCarthy (1988). McCarthy reviewed the various properties that have traditionally been seen as diagnostics of autosegmental representation, including the following:

(3) a. Assimilation
b. Dissimilation
c. Floating features
d. Contour features
e. Single-feature morphemes

Figure 2 One place node characterizes two sounds in the Spanish word *ninfa*.

Figure 3 The spread of [coronal] entails spread of its dependent features.

He pointed out that while some features (e.g., those characterizing tone, place of articulation, voicing) satisfy some or all of these diagnostics across languages, at least two apparently do not: the major class features [±sonorant] and [±consonantal]. If we place these features on separate autosegmental tiers, we will incorrectly predict that they will exhibit some or all of the properties listed in (3). In order to exclude this possibility, McCarthy proposed that [±sonorant] and [±obstruent] should be features of the root node, rather than autonomous features in the autosegmental sense. While this proposal has been contested (for discussion of [±consonantal], see especially Kaisse, 1992), counterexamples have proven scarce, and it has tended to be widely accepted. However, this result requires a modification of statement (1d), restricting it only to those features that exhibit autosegmental properties such as those listed in (3).

A second important development comes from articulator theory, as developed by Sagey (1990) and Halle (1995). Halle noted that autosegmentally represented features can be divided into two types: those that depend for their execution on one or another of the articulators ([labial] = lips; [coronal] = tongue front; [dorsal] = tongue body, etc.), which they term *articulator dependent*, and those that are not, which they term *articulator free*. Examples of articulator-dependent features are [±anterior] and [±distributed], which are executed exclusively by the tongue-front articulator [coronal], and examples of articulator-free features include [±continuant] and [±consonantal], which can be executed by any of several articulators. Regarding the first, Sagey observed that whenever one segment assimilates to another in coronality, its dependent features of [±anterior] and [±distributed] always spread along with it. For example, if a labial sound such as *m* assimilates to a nonanterior coronal sound such as [tʃ], it will become not only coronal (for this, a shift to [n] would suffice) but also nonanterior (postalveolar). This regularity can be expressed by placing [±anterior] and [±distributed] under [coronal] as *dependents*, as shown in Figure 3.

Given this representation, the spread of [coronal] to a preceding segment, as indicated by the dashed line, will entail the spread of its dependent features as well. In contrast, the higher-level features [±continuant] and [±nasal] are unaffected. In general, as this example illustrates, higher-level structure tends to remain stable under processes that affect lower-level structure – another strong and apparently correct claim of feature geometry.

A further innovation in Sagey's work is the classification of speech sounds into three types: *complex segments*, containing two unordered place specifications; *contour segments*, containing two internally sequenced features; and *simple segments* comprising all others. Complex segments include the labial-velar stops *kp* and *gb* of many sub-Saharan African languages (as shown in Figure 1) or the clicks of many South African languages, both of which combine a velar closure with another closure located further forward in the mouth, as well as consonants with minor (or secondary) articulations, such as labialized k^w. Contour segments include affricates, such as t^s, containing successive [−continuant] and [+continuant] components, and prenasalized stops,

Table 3 A single set of place features for consonants and vowels

Feature	*In consonants*	*In vowels*
[labial]	labials, labialized consonants	rounded vowels
[coronal]	coronals, palatalized consonants	front and retroflex vowels
[dorsal]	velar and uvular consonants, velarized and emphatic consonants	back vowels
[pharyngeal]	uvular and pharyngeal consonants, pharyngealized and emphatic consonants	pharyngealized vowels

such as ^{n}d, containing successive [+nasal] and [−nasal] components. The recognition of contour segments greatly extends the expressive power of the theory, and for this reason they have come under close scrutiny; it now appears, for example, that affricates can be reanalyzed as simple stops with no [+continuant] component (see Kehrein, 2002, and references therein).

A third development in feature geometry is unified place theory, as summarized in Hume (1994), Clements and Hume (1995), and references therein. The basic innovation of this approach is its use of a single set of articulator features to express related places of articulation in vowels and consonants, as shown in Table 3.

(Note that uvulars are characterized as both [dorsal] and [pharyngeal].) This approach captures the close phonological relationship between homorganic consonants and vowels by assigning them the same features. Thus, rounded vowels share the feature [labial] with labial consonants; front vowels share the features [coronal] and [−anterior] with palatal consonants; back vowels share [dorsal] with velar and uvular consonants; and so forth. This analysis allows common processes of consonant/vowel place assimilation to be expressed as the spreading of Place features. For example, the shift of /pi/ to [pu] is characterized as the spread of [labial] from the consonant to the vowel, while velar palatalizations such as /ki/ > [ci] are characterized as the spread of [coronal, −anterior] from the vowel to the consonant. A formal consequence of this approach with respect to earlier work is that features such as [labial] and [coronal] must be allowed to link to two different tiers of structure (C-place in the case of consonants and V-place in the case of vowels and secondary articulations), requiring a weakening of principle (1e). This innovation is needed to express the transparency of consonants to many types of vowel spreading; for example, rounding harmony in Turkish vowels is not blocked by labial consonants like *p*, as would be predicted under the no-line-crossing constraint of autosegmental phonology if [labial] were linked to the same tier in consonants and vowels.

Table 4 Relationships between different types of consonants

Consonants	*Tones*	*Halle/Stevens features*
Voiced obstruents	Low (or extra-low) tones	[+slack vocal cords]
Voiceless obstruents	High tones	[+stiff vocal cords]

Two attempts have been made to express the consonant/vowel relations in Table 3 while maintaining principle (1e) as well as the traditional vowel features [±back, ±round]. In the model proposed by Ní Chiosáin and Padgett (1993), consonant place features are represented twice: once on a consonantal tier of structure, where they constitute primary place features, and again on a vocalic tier, where they act as "virtual" secondary place features. A basic claim of this model is that only the latter interact directly with vowels; thus, the shift of /pi/ to [pu] represents the spread of the secondary labial feature [+round] from the consonant to the vowel. Velar palatalizations, such as /ki/ > [ci], are handled by a separate mechanism of restructuring. In a proposal by Halle *et al.* (2000), developing earlier work by Halle (1995), the shift of /pi/ to [pu] involves the spread of the terminal feature [labial], as in the Clements/Hume model, but the output is subjected to restructuring by a set of equivalency relations so that the resulting [u] bears the feature [+round] instead of [labial]. Palatalizations are handled analogously. As the restructuring conventions required in both models carry out rather substantial surgery on feature trees, both require at least a limited violation of the constraint in (2).

A closely related and equally controversial question in feature organization concerns the correct expression of the close relations between certain consonant types and tones. Observations from a number of tone languages in Asia and Africa have brought to light the common (though not universal) relationships between consonants and tones shown in the first two columns in Table 4.

For example, in many tone languages, voiced obstruents are found to trigger low tones on following vowels or to block the spread of high tones across them (just as they would do if they bore low tones).
